Editorial

At its meeting on 8 June 2000 the Governing Council decided to raise the ECB interest rates by 50 basis points. The interest rate on the Eurosystem's main refinancing operations was raised from 3.75% to 4.25%. This rate will be applied in the two operations (which will be conducted as fixed rate tenders) to be settled on 15 and 21 June 2000 respectively. The interest rates applicable to the deposit and marginal lending facilities were raised to 3.25% and 5.25% respectively, with effect from 9 June 2000.

The Governing Council also decided at its meeting on 8 June 2000 that, starting from the operation to be settled on 28 June 2000, the main refinancing operations of the Eurosystem would be conducted as variable rate tenders, applying the multiple rate auction procedure. The Governing Council has decided to set a minimum bid rate for these operations equal to 4.25% (i.e. the same rate as that prevailing for fixed rate tenders following the rise in interest rates on 8 June 2000).

By its decision to raise ECB interest rates the Governing Council acted in a forward-looking manner, in order to contribute to the maintenance of favourable conditions for a lasting, non-inflationary economic expansion. In the months prior to the move, the upside risks to price stability in the medium term had clearly been increasing. This assessment was supported by the information from both pillars of the Eurosystem's monetary policy strategy. With regard to the first pillar, strong growth of monetary and credit aggregates throughout 1999 and the pronounced further expansion over the first four months of 2000 strengthened the view that liquidity is ample. As for the second pillar, in a phase of strong growth upward pressures on consumer prices stem mainly from rising import prices which, in turn, reflect the lagged effects of the depreciation of the exchange rate of the euro and higher oil prices. In fact, most inflation forecasts were revised upwards in early 2000.

Considering, in the context of the first pillar, the most recent information on monetary

developments in more detail, the threemonth average of the annual growth rates of M3 (covering the period from February to April 2000) was 6.3%, compared with 5.9% in the period from January to March 2000. There has thus been a further deviation of M3 growth from the reference value of $4\frac{1}{2}$ %. The rather strong increase in recent months was consistent with the available indicators on the strength of economic activity. The annual rate of increase in credit to the private sector has also remained high, rising in April to 11.4%, from 10.9% in the previous month. Overall, the latest monetary and credit data confirmed that liquidity in the euro area continued to be very generous. Such developments would point to upside risks to price stability over the medium term if not counteracted in time.

Information from the second pillar, including economic and financial market developments, and developments in the Harmonised Index of Consumer Prices (HICP), is consistent with this assessment stemming from the monetary analysis. Recent news on the economic situation in the euro area, such as that available from industrial production various surveys, provides further and confirmation of the strength of the economic expansion under way and indicates that the outlook for growth in the euro area has improved markedly in the past few months, following the upturn in real GDP growth since the second half of 1999. The results of Business and Consumer Surveys from the European Commission, for example, support this assessment, with both indicators rising in May to record high levels. Consistent with this picture of a further improvement in economic conditions, major international and private sector institutions have tended to revise upwards their forecasts for economic growth in 2000 and 2001. Real GDP growth is now widely projected to rise from just below $2\frac{1}{2}\%$ in 1999 to over 3% both this year and in 2001. Labour market conditions have also improved in recent months. Employment growth continued to be positive around the turn of the year, and the rate of unemployment fell to 9.2% in April 2000.

The improved outlook for economic growth in the euro area reflects favourable conditions for both domestic and external demand. Domestic demand is expected to benefit, inter alia, from ongoing employment growth and higher rates of capacity utilisation. In addition, net exports are expected to be strong, as the external environment has continued to strengthen in the past few months, and the global economic upswing currently under way now appears more robust and broadly based than expected at the end of last year.

Considering recent developments in financial markets, long-term bond yields declined in May and early June. Given the pronounced rise in money market rates there was some flattening in the yield curve in the course of May. However, the slope of the yield curve remained positive, consistent with market expectations of continued robust growth in the euro area.

The exchange rate of the euro appreciated towards the end of May and in early June. This seemed to be mainly due to the market perception that the declining trend in the external value of the euro did not reflect the improved economic situation and prospects for the euro area and was not consistent with international balance of payments positions. Nevertheless, given the extent and duration of the earlier depreciation, further upward pressure on consumer prices is to be expected.

The annual increase in the HICP was 1.9% in April 2000, compared with 2.1% in the previous month. Given the significant increase in import prices which has occurred, mainly on account of the lower exchange rate of the euro and higher oil prices, the rate of increase in the HICP is not expected to fall back significantly in the near future. In an environment of strong growth and increasing capacity utilisation, the pass-through of exchange rate changes via import prices to consumer prices is facilitated. Against this background, the decision to raise ECB interest rates has been a firm and forward-looking step, taken to counter the increasing upward risks to price stability which had emerged in the months prior to the move. This should help economic agents to rely firmly on the maintenance of price stability, which is the most important contribution that the Eurosystem can make towards sustaining non-inflationary growth in the euro area in the medium term.

The prospects for sustaining non-inflationary growth in the euro area also depend to a large extent on labour market developments. It remains a major challenge to reduce the level of unemployment in the euro area which, despite some decline, remains too high. In this respect, both appropriate wage settlements and structural reforms are important contributions to continued employment growth and to maintaining low inflation.

The euro area outlook also very much depends on the course of fiscal policy. The pace of the reduction in fiscal deficits is expected to slow down in both 2000 and 2001. Moreover, the only slight reduction in fiscal deficits over this period masks some deterioration in cyclically adjusted fiscal positions for the euro area as a whole. This deterioration in the structural budget balance indicates a pro-cyclical loosening of the stance of fiscal policy, largely resulting from planned tax reforms in conjunction with insufficient control of discretionary government expenditure. While tax reforms are welcome, more emphasis should be given to structural reform on the expenditure side of budgets leading to strict expenditure restraint. At the current juncture, a pro-cyclical bias in fiscal policies should be avoided as it would give rise to an inappropriate stimulus to aggregate demand raising the risk of inflationary pressures. This is particularly important in those countries where there is a risk of overheating. Furthermore, the high level of public sector debt in many euro area countries remains a cause for concern. especially against the background of long-term

challenges to public finances, such as that arising from the ageing of populations. The opportunity presented by the current economic environment to set public finances on a sounder footing must not be missed.

With regard to the switch to variable rate tenders in the main refinancing operations, this is not intended to be a change in the monetary policy stance of the Eurosystem. The new tender mechanism is a response to the severe overbidding which has developed in the context of the fixed rate tender procedure applied so far. For the purpose of signalling the monetary policy stance, the minimum bid rate is designed to play the role performed, until now, by the rate in fixed rate tenders. This change to a variable rate tender does not in any way rule out the option that, in the future, the main refinancing operations of the Eurosystem may be conducted as fixed rate tenders.

Economic developments in the euro area

I Monetary and financial developments

Monetary policy decisions of the Governing Council of the ECB

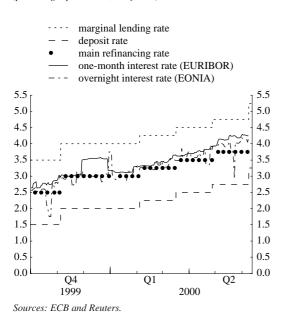

At its meeting on 8 June 2000 the Governing Council of the ECB decided to increase the ECB interest rates by 50 basis points. The Governing Council announced that the main refinancing operations to be settled on 15 and 21 June 2000 would be conducted as fixed rate tenders at an interest rate of 4.25% (the previous level of the main refinancing rate was 3.75%). The interest rates on the deposit facility and on the marginal lending facility were also raised, from 2.75% to 3.25% and from 4.75% to 5.25% respectively (see Chart 1).

At the same meeting the Governing Council also decided that, starting from the operation to be settled on 28 June 2000, the main refinancing operations of the Eurosystem would be conducted as variable rate tenders, applying the multiple rate auction procedure. The Governing Council decided to set a minimum bid rate for these operations equal to 4.25%. This is the same rate as that

Chart I

ECB interest rates and money market rates

(percentages per annum; daily data)

announced to apply in the two fixed rate tenders with settlement on 15 and 21 June 2000.

The switch to variable rate tenders in the main refinancing operations is not intended as a further change in the monetary policy stance of the Eurosystem, but rather as a technical move. In fact, the new tender mechanism is a response to the severe overbidding which affected the main refinancing operations of the Eurosystem, as conducted on the basis of the fixed rate tender procedure. Since early 2000 the bids submitted had been following a steady upward trend, leading to a situation in which in tender allotments in late May and early June less than 1% of the bids could be satisfied by the Eurosystem.

With the new procedure the Eurosystem's counterparties which participate in the auction for the allotment of liquidity will submit their bids indicating not only the amount of liquidity they are requesting, but also the rate of interest they would be prepared to pay for it. In this context, counterparties will need to submit bids at rates at or above the minimum bid rate of 4.25% set by the Eurosystem. The Eurosystem will determine the amount of liquidity it will provide to the market. It will satisfy the bids with the highest interest rate with priority and will successively accept bids with lower interest rates until the total liquidity to be allotted is exhausted. This tender procedure, which foresees that the allotment of liquidity to individual counterparties will depend on the level of the interest rate at which bids are submitted, implies that counterparties' bidding behaviour will be constrained by interest rate cost considerations.

In designing the new tender procedure, emphasis has been placed on maintaining the possibility for the Governing Council to send a clear signal about the monetary policy stance through the rates applied to the main refinancing operations. This has been done by announcing a minimum bid rate. For the purpose of signalling the monetary policy stance, the minimum bid rate is designed to play the role performed, until now, by the rate in fixed rate tenders.

The Governing Council has deliberately chosen to start with the new procedure only as from the first main refinancing operation to be settled in the reserve maintainance period starting on 24 June 2000. This should facilitate counterparties' preparations for the change.

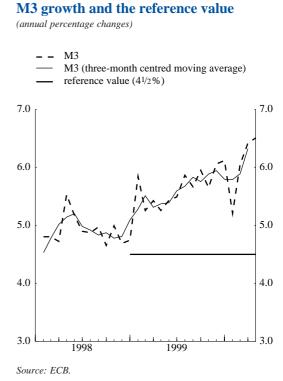

Finally, the Governing Council stressed that the switch to variable rate tenders does not in any way rule out the possibility that, in the future, the main refinancing operations of the Eurosystem may be conducted again as fixed rate tenders.

Increasing deviation of M3 growth from the reference value in April 2000

In April 2000 the annual rate of increase of the broad monetary aggregate M3 stood at 6.5%, compared with 6.4% in March 2000 (the latter figure was revised downwards from 6.5%). The three-month average of the annual growth rates of M3 increased to 6.3% over the period from February to April 2000, up from 5.9% in the period from January to March (the latter figure was revised downwards from 6.0%). As a consequence, the deviation of M3 growth from the reference value of $4\frac{1}{2}$ % rose to almost 2 percentage points (see Chart 2).

The month-on-month rise in M3 in April 2000 was \in 41 billion. This increase was partly attributable to seasonal influences. It is estimated that, in seasonally adjusted terms, M3 grew by \in 19 billion, or 0.4%, in April 2000 (see Table 1). The expansion in M3 in April was, therefore, relatively moderate, and less pronounced than in the previous three months. However, this does not change the assessment that the short-term dynamics of M3 have been rather strong over recent months. Indeed, the seasonally adjusted and

Chart 2

annualised six-month growth rate of M3 remained high, standing at 7.1% in April, compared with 7.3% in the previous month. Although the pronounced increase in M3 may have been influenced by the flattening of the yield curve since the end of January, the main factor contributing to this development seems to have been the robust economic growth in the euro area, both in nominal and in real terms.

With regard to its components, M3 growth in early 2000 was very much driven by its most liquid elements (see Chart 3). The annual rate of growth of the narrow monetary aggregate M1 rose to 11.4% in April, compared with 10.2% in March. The seasonally adjusted and annualised six-month growth rate of M1 increased to 13.0% in April. With regard to the components of M1, the annual rate of growth of currency in circulation increased to 5.5% in April 2000, from 5.2% in the previous month. At the same time, the very pronounced pace of growth of overnight deposits observed since the beginning of the year continued in April.

Source: ECB

Note: Due to rounding, the sum of the components of M3 in euro (billions) may not add up to the total reported for M3.

As a consequence, the annual rate of growth of this component rose significantly (to 12.6%, from 11.2% in March 2000). The strong growth in overnight deposits, which occurred in spite of the recent widening of the spread between short-term market interest rates and retail bank interest rates on overnight deposits, may indicate continuing robust economic growth in the euro area. In addition, the heightened preference for liquidity may, in part, have mirrored a precautionary motive, given the relatively high uncertainty in the euro area stock markets during the first four months of 2000 (see Table 3 at the end of the stock market section). Finally, the pronounced expansion of overnight deposits might also, to a certain extent, be the counterpart of some frontloading of loans in expectation of rising short-term interest rates (see below).

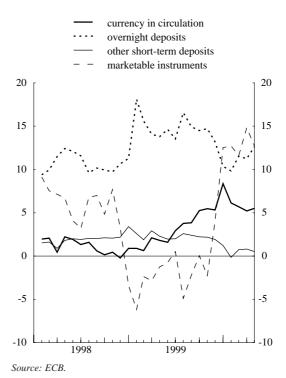

The annual growth rate of short-term deposits other than overnight deposits decreased in April 2000, to 0.5%, from 0.8% in March. This reflected the fact that the annual rate of change in deposits redeemable at a period of notice of up to three months turned negative (it stood at -0.1%, compared with 0.9% in the previous month). The continuing downward trend in the demand for these instruments, which started in the last few months of 1999, is presumably a result of their currently low attractiveness in

terms of yields. Since the summer of last year the spread between short-term market rates and retail interest rates on deposits with an agreed maturity of up to two years, on the one hand, and retail rates on deposits redeemable at a period of notice of up to three months, on the other, has increased

Chart 3

Components of M3

(annual percentage changes)

significantly. At the same time, these interest rate developments may also partly explain the recovery in the demand for deposits with an agreed maturity of up to two years in recent months. The annual rate of growth of these deposits rose in April 2000 (to 1.3%, from 0.6% in the previous month). The demand for deposits with an agreed maturity of up to two years might also have been encouraged by the flattening of the yield curve and by precautionary motives. As a consequence of the increase in the annual growth rate of MI, and despite the decline in that of short-term deposits other than overnight deposits, the annual rate of increase in the intermediate aggregate M2 rose to 5.5% in April 2000, compared with 5.1% in March.

The annual rate of growth of the marketable instruments included in M3 declined in April 2000, to 12.7%, from 14.8% in the previous month. With regard to the individual items, the annual growth rate of money market fund shares and money market paper fell to 13.6%, from 19.5% in March. The annual rate of increase in debt securities issued with a maturity of up to two years declined to 37.7%, compared with 40.0% in the previous month. The annual rate of change in repurchase agreements turned positive for the first time since October 1998 (to 2.7% in April 2000, following -2.3% in the previous month).

Continued strong growth of credit to the private sector

Turning to the counterparts of M3, the annual rate of increase in long-term financial liabilities remained virtually constant in April 2000, standing at 6.9% (compared with 7.0% in March). Among the sub-components of longer-term financial liabilities, the annual rate of growth of deposits with an agreed maturity of over two years declined slightly to 4.0%, from 4.2% in the previous month. The annual growth rate of debt securities issued with a maturity of over two years was 5.6%, following 5.7% in the previous month.

Deposits redeemable at a period of notice of over three months continued to decline, albeit at a slower annual pace (4.6% in April, compared with 6.0% in March). Finally, the annual growth rate of capital and reserves remained broadly unchanged at 15.2%.

On the assets side of the consolidated balance sheet of the MFI sector, the annual growth rate of total credit granted to euro area residents increased from 7.8% in March to 8.1% in April. This rise was exclusively due to stronger growth of credit to the private sector (the annual growth rate of which reached 11.4%, up from 10.9% in the previous month). By contrast, the annual rate of change in credit to general government declined further (to -1.3%, from -0.8% in March).

The sustained growth of credit to the private sector reflected an increase in the annual growth rate of loans (to 10.3%, from 9.7% in March). The strong dynamics of loans over recent months is also confirmed by the evolution of the seasonally adjusted and annualised six-month growth rate, which stood at 11.0% in April, compared with 10.1% in the previous month. Robust economic growth both in real and in nominal terms has contributed to sustaining the demand for loans from the private sector in recent months. Moreover, the strong merger and acquisition activity and the interaction between mortgage loans and the rise in real estate prices in some euro area countries have also fostered the strong increase in loans. In addition, despite the continuous rise in nominal lending rates, real retail lending rates (as measured on the basis of current HICP inflation) are currently below the level they reached at the end of 1998. Hence financing conditions in the euro area are very favourable at the current juncture. Finally, the possibility of some frontloading of loans motivated by expectations of rising shortterm interest rates cannot be ruled out. Quarterly data available up to March 2000 provide a breakdown by sector of loans to euro area residents (see Box I). These data indicate that the increase in the growth of loans to the private sector in the first quarter

Box I Developments in the sectoral breakdown of MFI loans in the first quarter of 2000

Quarterly data on the breakdown of MFI loans granted to euro area residents by counterpart sector, type and original maturity are released in this issue of the ECB Monthly Bulletin up to the first quarter of 2000. While these data provide a reliable picture of the structure of the MFI loans at a certain point in time, it has to be taken into account that these data only allow annual growth rates to be calculated on the basis of changes in stocks outstanding. These annual growth rates are not directly comparable with those reported for the total of MFI loans in the main text, since the latter are corrected for reclassifications, revaluations and write-offs/ write-downs of loans. Nonetheless, the analysis of changes in stocks should be seen as providing the best possible estimation of the sectoral dynamics of loans available.

The annual rate of growth of total loans to euro area residents calculated on the basis of changes in stocks reached 8.4% in the first quarter of 2000, following 8.1% in the final quarter of 1999. As shown in the table below, this increase masked differences in trends across sectors. On the one hand, there was a rise in the annual growth rate of loans to non-financial corporations (to 10.3% in the first quarter of 2000, up from 8.4% in the last quarter of 1999). On the other hand, the growth rate of loans to households fell slightly, from 10.0% in the last quarter of 1999 to 9.5% in the first quarter of 2000, while remaining at a very high level. The growth rate of loans to non-monetary financial corporations (insurance corporations and pension funds and other financial intermediaries) also fell, to 8.5% in the first quarter of 2000, down from 10.3% in the last quarter of 1999. Finally, the annual growth rate of loans to general government became negative in the first quarter of 2000, at -0.5%, following 0.7% in the fourth quarter of 1999.

As noted above, loans to non-financial corporations increased significantly in the first quarter of 2000. This development may be associated with the improvement in industrial confidence indicators and the strengthening of economic activity in the euro area. Moreover, it is likely that merger and acquisition transactions have continued to stimulate the demand for loans from non-financial corporations. The strong expansion in the first quarter of this year concerned both loans with an original maturity of up to one year (which increased on an annual basis by 9% in the first quarter of 2000, up from 7.2% in the fourth quarter of 1999) and loans with an original maturity of over five years (9.9% in the first quarter of 2000, compared with 8.1% in the last quarter of 1999). By contrast, loans with intermediate maturity (the share of which is small in relation to the total) showed stable annual growth rates at a high level (around 15%) over the same period. It is to be stressed that real lending rates were low by historical standards in the first quarter of 2000, especially for short-term loans. In the first quarter of 2000 the real lending rate for loans with a maturity of less than one year, calculated as the difference between the nominal interest rate and the HICP inflation rate, was 3 percentage points below the average real lending rates observed from January 1990 to March 2000. The corresponding real lending rate for loans with a maturity of 2000, 0.7 percentage point below the average observed from January 1990 to March 2000.

Regarding loans to the household sector, while the overall growth rate declined slightly, the growth rate of consumer loans increased from 5.7% in the fourth quarter of 1999 to 6.5% in the first quarter of 2000. This increase could be linked to the further improvement in economic activity and consumer confidence observed since the last quarter of 1999. At the same time, the retail rates on consumer credit have risen only slightly over the past few quarters in nominal terms and have remained low in real terms. The annual growth rate of loans for house purchase remained unchanged at a high level (12.1%), in spite of the continuous rise in nominal lending rates between May 1999 and March 2000 (+130 basis points). This can partly be explained by the fact that the lending rates for house purchase remained, in real terms, relatively low by historical standards (the real lending rate on loans for house purchase in the first quarter of 2000, calculated using the HICP inflation rate, was about 1.5 percentage points below the average real lending rate observed from January 1990 to March 2000). Moreover, the dynamic pace of growth in loans for house purchase also seems to interact with buoyant housing markets in some countries.

Finally, the sectoral data show that the decline in the annual rate of change in loans to general government in the first quarter of 2000 was mainly related to a substantial fall in the rate of change in loans to central government (to -10.7%, from -0.8% in the fourth quarter of 1999). By contrast, the annual growth rates of loans to state government rose from 0.2% in the fourth quarter of 1999 to 4.3% in the first quarter of 2000 and the annual rate of change in loans to local government remained broadly unchanged, at slightly above 1%. The overall reduction in loans to general government reflects both lower borrowing requirements and also a continuation of the observed trend of a longer-term decrease in the share of loans in the total financing of general government.

Note: Due to rounding, the sum of the counterparts of M3 in euro (billions) may not add up to the total reported for M3.

of 2000 was mainly driven by the evolution of loans to enterprises. These data also show that the growth rates of loans for house purchase remained at the high level reached at the end of 1999.

By contrast with the rise in the growth of loans, the annual growth rate of MFI holdings of securities issued by the private sector declined slightly, although it remained at a high level. The annual growth rate of MFI holdings of debt securities was 16.4% in April 2000, down from 17.5% in March 2000, while that of holdings of shares and other equity amounted to 24.7%, compared with 25.8% in March 2000.

As for credit to general government, the annual rate of change was negative in April 2000, at -1.3%, following -0.8% in March. This reflected offsetting moves of MFI holdings of government debt securities – which declined by 2.9% compared with a year earlier, following a fall of 1.2% in March – and loans to general government (which increased by 1.0%, compared with -0.3% in the previous month).

In April 2000 the net external asset position of the euro area MFI sector decreased by \in 32 billion, following a decrease of \in 68 billion a month earlier, in absolute and non-seasonally adjusted terms.

Overall, credit to the private sector rose by ${\in}658$ billion over the 12 months to April

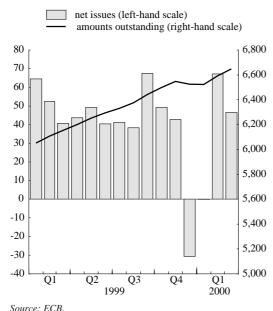

2000. By contrast, credit to the public sector declined by $\in 27$ billion and net external assets by $\in 202$ billion. The resulting net increase on the assets side of the consolidated balance sheet of the MFI sector was associated, on the liabilities side, with growth of M3 amounting to $\in 297$ billion and an increase in longer-term MFI liabilities of $\notin 237$ billion. The other developments in the remaining items of the MFI balance sheet resulted in a decline in net liabilities of $\notin 105$ billion (see Table 2).

Debt securities issuance remained high in March

In March 2000 the gross issuance of debt securities by euro area residents totalled \in 389.6 billion, compared with an amount of €306.6 billion in March 1999 and average monthly gross issuance of \in 313.0 billion over the previous 12 months. Redemptions in March 2000 amounted to \in 343.1 billion. As a result, net issues in March totalled €46.5 billion (see Chart 4). This was higher than the net issuance of \in 40.7 billion in March 1999 and the average monthly issuance of \in 37.5 billion over the previous 12 months. Reflecting these developments, the amount outstanding of debt securities issued by euro area residents had increased to \in 6,648.3 billion by the end of March 2000. This was 8.0% higher than a year earlier and compared with an annual rate of increase of 7.9% in February.

Debt securities issued by euro area residents

(EUR billions)

Note: Net issues differ from the change in amounts outstanding owing to valuation changes, reclassifications and other adjustments.

The relatively high net issuance of debt securities by euro area residents in March mainly reflected significant issuance of shortterm debt securities (maturities of less than one year). Reflecting this, the annual growth rate of the amount outstanding of short-term debt securities increased from 9.7% in February to 12.5% in March. At the same time, since net issuance of long-term securities was somewhat lower than the average of the previous 12 months, the annual growth rate of the amount outstanding of long-term debt securities declined to 7.6% in March, from 7.8% a month earlier.

Data on the sectoral breakdown reveal that issuance activity by the MFI sector, which has been rising more or less continuously since August 1999, was particularly strong in March. Reflecting this, the annual rate of increase in the amount outstanding of euro denominated debt securities issued by the MFI sector increased from 10.4% in February 2000 to 10.8% in March. This increasing issuance activity by MFIs might reflect increasing recourse by MFIs to market sources of finance, in the face of a more rapid increase in credit demand than in deposits. At the same time, the annual rate of increase in the amount outstanding of euro denominated debt securities issued by central government declined slightly in March, to 3.5%, from 3.6% in the previous month. In other sectors, the annual growth rate of the amount outstanding of debt securities issued by non-monetary financial corporations continued at a high rate of 41.3% in March, compared with 41.2% one month earlier. The annual growth rate of the amount outstanding of euro denominated debt securities issued by non-financial corporations declined from 9.2% to 7.8% in March 2000.

Short-term retail bank interest rates increased further in April

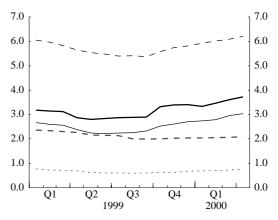

Short-term retail bank interest rates in the euro area continued to increase in April 2000 against the background of increases in money market interest rates and in ECB interest rates on 16 March and 27 April (see Chart 5). The average interest rate on

Chart 5

- deposits with an agreed maturity of up to one year
- deposits redeemable at notice of up to three months
- ---- overnight deposits

Sources: ECB aggregation of individual country data and Reuters.

deposits with an agreed maturity of up to one year increased by 9 basis points in April to over 3.0%. Somewhat smaller increases were observed in the average rates on overnight deposits and deposits redeemable at a period of notice of up to three months. The average rate on loans to enterprises with a maturity of up to one year increased by 13 basis points to reach 6.2% in April 2000. Seen over a longer period, since September 1999 short-term retail bank interest rates have increased by considerably less than comparable market interest rates, reflecting the lagged and gradual pattern in the adjustment of retail bank interest rates to changes in market interest rates. However, overall, all short-term retail bank interest rates in April 2000 were above the levels prevailing a year earlier, with the exception of the average interest rate on deposits redeemable at a period of notice of up to three months.

At longer maturities, average retail bank interest rates have remained broadly unchanged since February 2000. This broad stability of long-term retail bank interest rates

Chart 6

Long-term retail bank interest rates and a comparable market rate

- - loans to households for house purchase

- - deposits with an agreed maturity of over two years

Sources: ECB aggregation of individual country data and Reuters.

in the euro area is notable against the background of a slightly declining trend in bond yields since January 2000. The average interest rate on deposits with an agreed maturity of more than two years stood at below 4.3% in April. At the same time, the average interest rate on loans to households for house purchase remained at 6.1%. In addition, the average rate on loans to enterprises was little changed in April, remaining below 5.9%. Despite their recent stability, all longer-term retail bank interest rates increased substantially after May 1999, and by April 2000 they stood at levels which were well above those prevailing one year ago (see Chart 6).

Money market interest rates continued to rise in May

Money market interest rates rose further in May 2000, continuing the upward trend which had been observed in March and April 2000. Between the end of February and the end of April short-term interest rates in the euro area rose, partly in anticipation of the increases in ECB interest rates which occurred on 16 March and 27 April 2000. While, during March and April, the main refinancing rate of the ECB was increased in two steps, by 50 basis points in total, the one-month and three-month EURIBOR rose by 47 and 46 basis points respectively during the same period (see Chart 7).

In the first few weeks of May 2000 the overnight interest rate, as measured by the EONIA, was quoted in a range of between 3.9% and 4.1%, i.e. somewhat higher than the then prevailing main refinancing rate of 3.75%, signalling some market expectations of an increase in ECB interest rates. This pattern was temporarily interrupted only towards the last few days of the reserve maintenance period ending on 23 May, when the EONIA fell to a level of 2.9%, as a consequence of abundant liquidity (see Box 2). At the start of the reserve maintenance period ending on 23 June 2000, the EONIA fluctuated again at levels above 4.0%, reflecting renewed

Box 2

Monetary policy operations and liquidity conditions in the reserve maintenance period ending on 23 May 2000

Allotments in monetary policy operations

During the fifth reserve maintenance period of this year, which ran from 24 April to 23 May 2000, the Eurosystem settled four main refinancing operations and one longer-term refinancing operation. The first main refinancing operation was carried out at a fixed interest rate of 3.50%, while the other three were carried out at a fixed interest rate of 3.75%, following the decision of the Governing Council on 27 April 2000 to raise ECB interest rates. The allotted volumes ranged between €64 billion and €89 billion. The amounts of bids submitted for the main refinancing operations varied between €4,625 billion and €6,574 billion, with an average of €5,761 billion, compared with an average bid amount of €3,615 billion in the previous reserve maintenance period. The further increase in the bid amounts submitted can be explained by strong interest rate expectations, as reflected, for example, in the spread between the two-week interbank deposit rate and the main refinancing rate. The allotment ratios in the main refinancing operations varied between 1.00% and 1.62%, compared with a range of between 1.36% and 2.94% in the preceding reserve maintenance period.

The Eurosystem settled a longer-term refinancing operation on 27 April through a variable rate tender with a pre-announced allotment volume of ≤ 20 billion. A total number of 326 bidders participated in this operation and the total amount of bids was ≤ 64 billion. The marginal rate was determined at 4.00%, while the average rate was 4.01%.

The EONIA remained above the main refinancing rate throughout the entire reserve maintenance period, with the exception of the last two days. For most of the reserve maintenance period the liquidity situation was relatively ample; however, on Friday 28 April one bank had to have recourse to the deposit facility for ≤ 10 billion over the long weekend including 1 May, resulting in an unexpected liquidity withdrawal of more than ≤ 40 billion in total. Although this incident tightened liquidity conditions around the end of the month, it is difficult to assess whether it had any impact on the EONIA. The main reason for the persistently high positive spread between the EONIA and the main refinancing rate, which was 18 basis points on average, was rate hike expectations. On both the penultimate and the last day of the reserve maintenance period the EONIA dropped, to 3.49% and 2.90% respectively, reflecting abundant liquidity.

Contributions to the banking system's liquidity

(EUR billions)

Daily average during the reserve maintenance period from 24 April to 23 May 2000

Liq	uidity providing	Liquidity absorbing	Net contribution
(a) Monetary policy operations of the Eurosystem	203.0	2.3	+ 200.7
Main refinancing operations	142.6	-	+ 142.6
Longer-term refinancing operations	60.0	-	+ 60.0

Totals may not add up due to rounding.			

Use of standing facilities

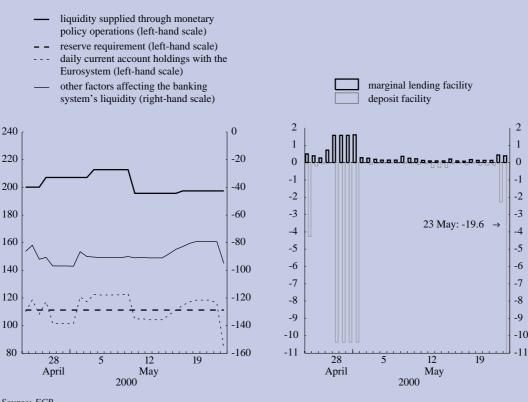

Compared with the previous reserve maintenance period, the average use of the marginal lending facility increased by $\in 0.2$ billion to $\in 0.4$ billion, while the average use of the deposit facility increased from $\in 0.9$ billion to $\in 2.3$ billion. The large increase in the use of the deposit facility was due to two factors: first, as mentioned above, there was exceptional recourse to the deposit facility by one bank because of technical problems and, second, recourse to the deposit facility was $\in 19.6$ billion on 23 May, the last day of the reserve maintenance period.

Liquidity factors not related to monetary policy

The net liquidity-absorbing impact of the autonomous factors (i.e. the factors not related to monetary policy) on the banking system's liquidity (item (b) in the table above) was \in 88.7 billion on average, i.e. \in 1.4 billion more than in the previous reserve maintenance period. This was mainly due to an increase in the amount of banknotes in circulation, the liquidity-absorbing impact of which was compensated in part by a decrease in net government deposits. On a daily basis, the sum of autonomous factors fluctuated between \notin 79.1 billion and \notin 96.9 billion.

Factors contributing to the banking system's liquidity during the maintenance period ending on 23 May 2000

(EUR billions; daily data)

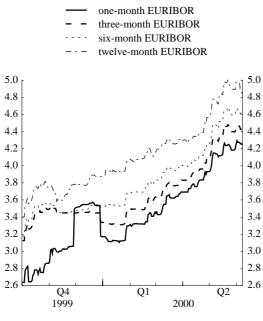

Source: ECB.

Current account holdings of counterparties

The average current account holdings amounted to $\in 112.0$ billion, and reserve requirements to $\in 111.3$ billion. The difference between the two therefore amounted to $\in 0.7$ billion. Around $\in 0.2$ billion of this amount was linked to current account holdings not contributing to the fulfilment of reserve requirements, and $\in 0.5$ billion was related to excess reserves. The latter were $\in 0.3$ billion lower than in the previous period, thus returning to their earlier level.

Short-term interest rates in the euro area (percentages per annum; daily data)

Source: Reuters.

expectations of higher ECB interest rates in the course of this maintenance period.

Other money market rates also rose between the end of April and 7 June, reflecting upward revisions of market expectations of the short-term evolution of ECB interest rates. On 7 June the one-month and three-month EURIBOR were equal to 4.24% and 4.41% respectively, approximately 30 basis points higher than their levels at the end of April. After increasing markedly during the first three weeks of May, short-term money market interest rates remained relatively stable. A broadly similar pattern was evident for the three-month EURIBOR implied in futures contracts maturing in June, September and December 2000. On 7 June the threemonth EURIBOR implied in the futures contracts maturing in June, September and December 2000 were equal to 4.43%, 4.70% and 4.97% respectively, which for all three rates was around 20 basis points higher than the levels recorded at the end of April. The six-month and 12-month EURIBOR were equal to 4.60% and 4.84% respectively on

7 June, which was around 30 basis points higher than at the end of April.

In the longer-term refinancing operation of the Eurosystem settled on I June 2000, the marginal and average interest rates of allotment were equal to 4.40% and 4.42% respectively. This was a few basis points below the three-month EURIBOR prevailing on the day on which the operation was conducted.

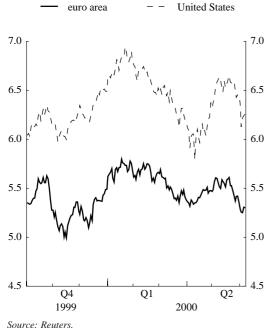

Long-term bond yields declined in May

By contrast with developments in April, euro area long-term government bond yields declined in May and early June 2000 (see Chart 8). Between the end of April and 7 June 2000 the average level of ten-year bond yields in the euro area fell by approximately 20 basis points, to around 5.30%. Taking a somewhat longer perspective, euro area long-term bond yields have declined by almost 50 basis points compared with the peak levels reached in January 2000, thereby returning to the levels prevailing in mid-December 1999. The spread between US and euro area ten-year bond yields increased slightly between the end of April and 7 June, when it stood at around 95 basis points, reflecting somewhat less pronounced declines in US bond yields than in the euro area during that period. During the first five months of 2000 the US-euro area yield spread displayed a high degree of variability, but the overall cumulative change was relatively minor, with the spread standing around 5 basis points lower on 7 June 2000 than at the end of 1999.

Considering the international environment for euro area bond markets, ten-year government bond yields in the United States were volatile between the end of April and 7 June 2000, with sharp increases in the first half of May being followed by similarly sharp decreases in the latter half of the month and in early June. Overall, US ten-year bond yields declined by approximately 10 basis points, to around 6.25%, between end-April and 7 June.

Long-term government bond yields in the euro area and the United States

(percentages per annum; daily data)

Note: Long-term government bond yields refer to ten-year bonds or to the closest available bond maturity.

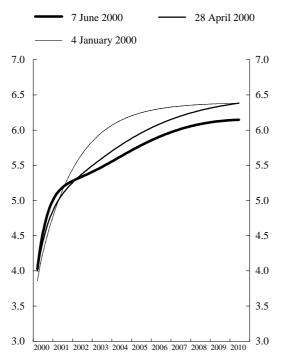

The increases in US bond yields which took place in the first half of May were a continuation of the upward trend that began in early April. This increase appeared to have been mainly linked to the continued strength of US economic activity and indications of upward price pressures, as well as to upward revisions on the part of market participants regarding the likely path of future short-term interest rates. This upward revision, in turn, was primarily triggered by data releases at that time, which indicated continued tightness in labour markets and signs of accelerating employment costs. In line with these expectations, the Federal Open Market Committee decided on 16 May to raise its target for the federal funds rate by 50 basis points. The accompanying statement, which concluded that risks remained "weighted mainly toward conditions that may generate heightened inflation pressures in the foreseeable future", may have contributed to placing additional upward pressure on longterm interest rates. Later on, new data releases, which appeared to indicate a possible slowdown in US economic activity, resulted in sharply lower long-term bond yields, as investors revised downwards both their inflation expectations and their expectations for the path of future shortterm interest rates.

In Japan ten-year bond yields declined by around 5 basis points between the end of April and 7 June, to somewhat above 1.7%, in an environment where sharp declines in Japanese stock prices seemed to have placed downward pressure on Japanese long-term bond yields, as investors sought safer investment opportunities.

While international factors seemed to have influenced short-term movements of euro area bond yields to some extent throughout much of May and early June, other factors also appear to have played an important role in explaining euro area bond yield developments during this period. During the month of May changes in euro area bond yields appeared to some extent to have been correlated with movements in the exchange rate of the euro, with euro exchange rate appreciation on average being associated with declining bond yields and vice versa. Furthermore, expectations that governments in some countries would use the proceeds from auctions of mobile telecommunications licences to reduce the level of outstanding public debt seemed to place downward pressure on bond yields in those countries. In addition to these factors, similar to a pattern seen in other major bond markets, long-term bond yields in the euro area were at times subject to downward pressure as a result of safe-haven-related flows from persistently volatile equity markets to bond markets. Furthermore, a possible reduction in long-term inflation expectations among market participants following increases in short-term interest rates which took place after the end of April may have contributed to the decline in euro area bond yields in May and early June.

Implied forward euro area overnight interest rates

(percentages per annum; daily data)

Source: ECB estimation. The implied forward yield curve, which is derived from the term structure of interest rates observed in the market, reflects the market expectation of future levels for short-term interest rates. The method used to compute these implied forward yield curves was outlined on page 26 of the January 1999 issue of the Monthly Bulletin. The data used in the estimation are derived from swap contracts.

As a result of declining long-term bond yields and pronounced increases in short-term money market rates, the euro area yield curve flattened markedly in the course of May, continuing a trend that had been evident since mid-January 2000. Between the end of April and 7 June the slope of the yield curve, as measured by the difference between euro area ten-year bond yields and the threemonth EURIBOR, declined by almost 50 basis points, to around 90 basis points. This brought this measure of the yield curve slope to a level that was around 125 basis points below that observed at the end of 1999, and to the lowest level seen since February 1999. At the same time, developments in the implied forward euro area overnight interest rate curve showed that the overall flattening of the yield curve was due to a pronounced steepening of the short end of the forward

yield curve, and a significant flattening of this curve at medium and long horizons (see Chart 9). It is particularly notable that long-horizon implied forward overnight rates have declined significantly, since this development is frequently seen as indicating a reduction in the long-term inflation expectations of market participants. All in all, the shape of the implied forward euro area overnight interest rate curve on 7 June suggested that short-term interest rates were expected by the market to increase at a more rapid pace than had been anticipated a month earlier, which, in turn, appears to have reduced long-term inflation expectations somewhat.

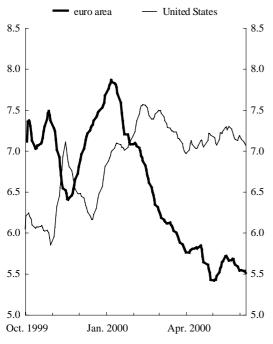

The relatively major changes in the shape of the yield curve which took place in May 2000 did not appear to have any significant impact on the market's perceived uncertainty regarding future movements in long-term bond yields. In fact, the implied volatility of the ten-year Bund futures contract, which provides a measure of the overall uncertainty associated with future price movements in the ten-year Bund, remained at a relatively low level, following a sizeable downward movement throughout the first few months of 2000 (see Chart 10). This may be seen as an indication that uncertainties regarding future real interest rates, future price pressures and inflation risk premia in the euro area are currently at a relatively low level, possibly reflecting a high degree of confidence among market participants about the growth prospects of the euro area economy and that appropriate monetary policy measures will be taken to ensure that price stability is maintained.

A similar picture emerges from the analysis of index-linked bonds in the euro area. Between the end of April and 7 June the "break-even" inflation rate, which can be calculated using French ten-year nominal and index-linked bonds, and which can provide indications of inflation expectations in the market, declined by around 15 basis points, while the real yield on the ten-year indexlinked bond was unchanged (see Chart 11).

Chart IO

Implied volatility for futures contracts on the ten-year German Bund and the ten-year US Treasury note

(percentages per annum; ten-day moving average of daily data)

Source: Bloomberg.

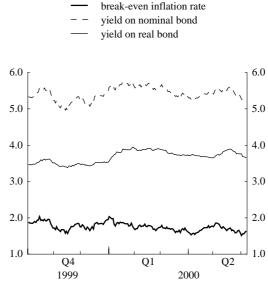

Note: The implied volatility series represent the nearby implied volatility on the near contract generic future, rolled over 20 days prior to expiry, as defined by Bloomberg. This means that 20 days prior to expiry of the contracts, a change in the choice of contract used to obtain the implied volatility is made, from the contract closest to maturity to the next contract.

This would seem to indicate that, while longterm real interest rates have remained stable at levels which seem to reflect optimistic growth expectations, inflation expectations over the long term appear to have declined somewhat. Hence the information derived from this indicator is consistent with developments in the euro area yield curve, which could be seen as pointing to market expectations of lower inflation in the long run, as a result of expectations of more pronounced short-term interest rate increases over the short horizon. As always, it should be borne in mind that any inference relating to euro area inflation expectations based on French index-linked bond yields warrants some degree of caution, since a number of caveats apply.

Chart II

Break-even inflation rate calculated for the French CPI

(in percentages; daily data)

Sources: French Treasury, ISMA and Reuters. Note: The real bond yields are derived from the market prices of French bonds which are indexed to the French CPI (excluding tobacco prices) and which mature in 2009. The nominal bond yields are derived from the market prices of French fixed income bonds which also mature in 2009.

Stock prices showed no discernible trend in May

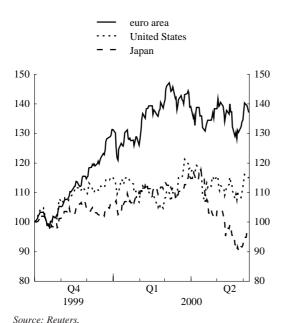

The high degree of volatility which had prevailed in global stock markets in April 2000 persisted in May and at the beginning of June. In this environment stock prices in the euro area and the United States showed no discernible trend between the end of April and 7 June. By contrast, in Japan stock prices continued to decline in May and early June (see Chart 12). All in all, when viewed over the five-month period since the end of 1999, stock price indices in both the euro area and the United States have shown little overall change, while in Japan they have fallen significantly.

Considering the international environment for stock markets, in the United States stock prices continued to be subject to large swings in May and at the beginning of June. Between the end of April and 7 June the Standard and

Chart I 2

Stock price indices in the euro area, the United States and Japan

(index: 1 October 1999 = 100; daily data)

Note: Dow Jones EURO STOXX broad (stock price) index for the euro area, Standard and Poor's 500 for the United States and Nikkei 225 for Japan.

Poor's 500 index increased by slightly more than 1%, reaching a level that was just above the levels seen at the end of 1999. Despite the release of corporate earnings data for the first quarter of 2000 which were slightly in excess of market expectations, in the first three weeks of May US stock prices seemed to be subject to mainly downward pressures, which were brought about by expectations of more rapid increases in US official interest rates in the remainder of 2000. In the last week of May and at the beginning of June, however, US stock prices recovered strongly following the release of economic indicators interpreted by market participants as indicating that the US economy was showing signs of slowing down.

Turning to sectoral developments in the US stock market, the high degree of volatility which had characterised the US technology sector earlier this year persisted in May and early June. In particular, the Nasdaq Composite index, which is laden with technology stocks, underwent considerable fluctuations throughout this period. Looking at developments over a longer period, on 7 June the Nasdaq Composite index reached a level which was some 24% below the peak level reached on 10 March and around 6% below the levels seen at the end of 1999. Furthermore, from a forward-looking perspective, the degree of stock market uncertainty in the US technology sector, as measured by implied volatility derived from stock option prices, increased further between the end of April and 7 June. Implied volatility on the Nasdag 100 index reached a level of 66% per annum on 7 June, compared with a level of 36% per annum, on average, in the second half of 1999.

In Japan stock prices declined considerably in May and at the beginning of June. When measured according to the Nikkei 225 index, Japanese stock prices fell by close to 8% between the end of April and 7 June, reaching a level which was 11% below that seen at the end of 1999. This development occurred despite the release of positive indications about future economic prospects. Over this period downward pressures on Japanese stock prices mainly affected the stocks of large Japanese firms active in the technology and telecommunications sectors. When considering developments since the end of 1999, however, Japanese stock price declines were rather broadly based across the consumer cyclical, industrial, technology and telecommunications sectors.

In the euro area, in May and at the beginning of June stock prices were subject to a relatively high degree of volatility, which seemed to spill over from the technology and telecommunications sectors, continuing a pattern that had already been seen in April. Overall, when measured by the Dow Jones EURO STOXX index, euro area stock prices declined by 1% between the end of April and 7 June. This left euro area stock prices at a level which was around 4% above the levels at the end of 1999. The high volatility seen in broad measures of euro area stock prices over recent months arose mainly from a high degree of volatility in the stock prices of firms in the technology and telecommunications sectors (see Table 3). Between the end of 1999 and 7 June 2000 historical volatility reached a level of 54% per annum in both of these sectors, compared with a level of 31% per annum and 27% per annum respectively, in the fourth quarter of 1999. Despite this high volatility, stock prices in the euro area technology sector showed an increase of 24% between the end of 1999 and 7 June 2000, while stock prices in the telecommunications sector showed a slight decline of about 1% over the same period. Hence, stock prices in the euro area technology and telecommunications sectors showed some resilience to the high

level of volatility which, particularly after March 2000, had become apparent in these sectors in global stock markets. Furthermore, stock prices in the euro area healthcare sector have increased steadily over recent months, against the background of high earnings growth expectations in these sectors. By contrast, between the end of 1999 and 7 June 2000 stock price developments in other economic sectors, such as the basic materials, industrial and consumer cyclical and non-cyclical sectors, were relatively weak in the euro area. At the same time, the volatility of stock price developments in these sectors was much lower than in the euro area technology and telecommunications sectors, although higher than in the fourth quarter of 1999.

2 Price developments

Energy prices led to a decrease in consumer price inflation in April

The overall rate of HICP inflation in the euro area fell from 2.1% in March to 1.9% in April 2000. This was a result of developments in energy and, to a lesser extent, processed food prices.

The annual rate of increase in the energy component stood at 10.5% in April 2000, substantially lower than the rate of 15.3% reached in March 2000 (see Table 4). This was mainly attributable to the base effect of the strong increase in energy prices from March to April 1999 and the increase in energy taxation in a larger country in April 1999. These developments exerted upward pressure on the energy index in April 1999 and hence had a downward effect on the year-on-year increase in April 2000. However, the fall in the energy price level from March to April 2000 also contributed to this, albeit to a lesser extent (i.e. only one-quarter of the total fall in the annual rate of increase from March to April 2000 of 4.8 percentage points). This is linked to the fall in oil prices from on average \in 28.4 per barrel in March to €24.6 per barrel in April 2000. No further strong downward impact on euro area HICP inflation from energy price developments can be expected for May 2000. First, base effects will have a slight upward effect on the annual rate of increase in the HICP energy

Box 3 Impact of import price developments on euro area consumer prices

Import unit value indices and nominal effective exchange rate of the euro

By contrast with the individual Member States, the euro area as a whole is a relatively closed economy. Imports of goods and services from the rest of the world correspond to 15% of euro area GDP, significantly less than for the individual euro area countries. This is the result of extensive trade within the euro area. However, even though the degree of openness in the euro area is smaller than for individual countries, import prices remain a factor which can potentially have a significant impact on euro area consumer price developments. This box explains three channels through which import price developments feed into euro area consumer price stability associated with recent import price developments.

A study of these channels is important because of recent developments in the prices of goods imported by the euro area from the rest of the world, which, as measured by import unit values, have risen significantly since late 1998, with an annual rate of increase of above 20% in early 2000.¹ On the one hand, this increase is attributable to developments in energy prices, which have risen strongly owing to developments in world market oil prices. On the other, the depreciation of the effective exchange rate of the euro has also contributed to the rise in import prices in general, as reflected in the developments in the import prices for non-energy raw materials and manufactured goods (see the chart below).

Note: Unit value indices refer to transactions between the euro area and the rest of the world; calculations are based on threemonth centred moving averages.

Three channels can be identified through which euro area import price developments are likely to affect the euro area HICP. These channels are (i) direct effects which occur almost immediately or, in other cases, with a short time-lag; (ii) indirect effects which arise as import price changes are gradually passed along the production chain; and (iii) possible second-round effects on wages and underlying inflation. It should be noted that the estimates of the impact on consumer prices via these three channels presented in this box are of a mechanical nature and, while being useful as an illustration of these effects, they should, therefore, be interpreted with caution.

The most prominent example of the *direct effects* on euro area consumer prices has recently been the impact of developments in the price of oil imports on the energy component of the HICP. As a reflection of oil price increases since the beginning of 1999, the annual rate of increase in the energy component of the HICP peaked

¹ Unit value indices are calculated by dividing the value by the volume of foreign trade and are not price indices based on data for the same basket of goods throughout the year (as is the case for consumer price indices). Nevertheless, in the absence of an alternative, import unit values are a useful indicator for developments in actual import prices.

at 15.3% in March 2000. The direct effects of higher prices for imported oil were most evident in the price of liquid fuels for households and fuels and lubricants for transportation. With regard to a quantitative impression of the direct effect of oil price changes on the HICP, a common rule of thumb is that a 10% increase in oil prices (measured in euro) is associated with an almost immediate 1% increase in the energy component of the HICP. Since energy has a weight of 9% in the HICP, such an increase in oil prices would tend to raise the overall HICP level by around 0.1%. In addition to energy prices, changes in the price of imported consumer goods may also have a direct effect on other individual items in the HICP. For example, imported passenger cars or photographic equipment (non-energy industrial goods) feed directly into private consumption without entering the domestic manufacturing process. However, foreign producers of these goods compete with domestic producers, and a price increase which fully reflects the exchange rate depreciation of the euro could lead to substantial losses in the market share on the part of foreign producers. This leads to the phenomenon known as "pricing to the market", according to which foreign producers charge different prices for their products depending on the price level in different countries. Therefore, in particular, short-term fluctuations in the exchange rate may not be reflected in the consumer price of these imported goods, while more sustained exchange rate changes are likely to be partially transmitted to consumer prices with a time-lag. While difficult to quantify, given the substantial and sustained depreciation of the euro over the past year, the direct effect of import prices of final goods is expected to materialise.

With regard to the *indirect effects* of changes in the price of imported goods, the prices of imported raw materials and also of imported intermediate goods affect the intermediate goods component of the euro area industrial producer price index. Such effects are likely to be particularly significant in the case of price increases for imported goods (such as oil), for which there are only limited possibilities available for substituting them for other inputs, and when the price of the domestic production of inputs closely follows world market price developments. Indeed, reflecting higher import prices, in the year to March 2000, intermediate goods prices in the euro area increased by 10.2%. Changes in intermediate goods prices are expected subsequently to affect industrial producer prices of final goods in the euro area (consumer and capital goods). Indeed, a rise in the annual rate of increase in the latter two components has occurred over recent months, albeit still at a moderate level. Finally, such effects on producer prices are, in turn, likely to have an impact on retail prices for consumer goods or services, as measured in the HICP. It will probably take some time before the above-mentioned indirect effects are fully incorporated into consumer prices at the retail level. A rough estimate based on historical experience suggests that the recent 20% increase in import prices, if sustained, is likely to contribute around 1 percentage point to the cumulative increase in euro area consumer prices via indirect effects over a two to three-year period. It should be noted that this comes in addition to the direct impact of import price developments as discussed above.

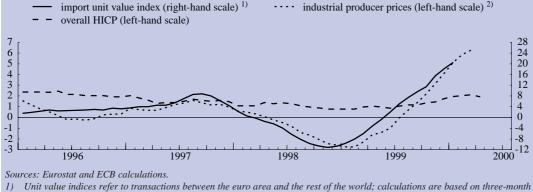

Finally, the occurrence and scale of possible *second-round effects* caused by changes in import prices is likely to depend on the complex interaction between wages, inflation expectations, the business cycle and the macroeconomic policy reaction. In addition to potential wage-price spirals, an exchange rate depreciation can lead to price pressures owing to an increase in economic activity as a result of the ensuing increase in competitiveness, which leads to growth in exports and a dampening effect on imports. Past experience suggests that second-round effects on inflation resulting from earlier oil price and exchange rate developments have, on occasion, been significant. In terms of inflation, the second-round effect will be smaller the less accommodating the monetary policy reaction. Both the current situation of strong economic growth in the euro area and the prospect that growth will be clearly above trend in the coming years point to substantial risks that recent import price increases may lead to second-round effects on euro area consumer price inflation. For further information on prospects for the euro area economy, see Box 4, which is entitled "A review of economic prospects for the euro area up to 2001" in the "Output, demand and labour market developments" section.

Overall, import prices have had a substantial upward impact on euro area consumer price inflation over the past year and are likely to continue to exert upward pressure on consumer prices (see the chart below). This is

a result of the time-lag with which import prices work through to consumer prices. In addition, there is a risk of second-round effects arising from developments in labour costs.

Consumer, producer and import prices in the euro area

(annual percentage changes; monthly data)

1) Unit value indices refer to transactions between the euro area and the rest of the world; calculations are based on three-month centred moving averages.

2) Excluding construction

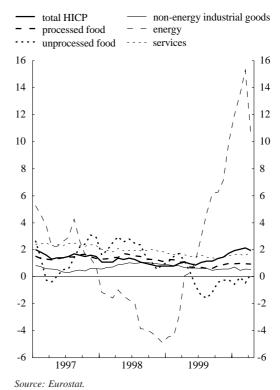

component in May 2000. Indeed, substantial negative base effects will not be seen again until the third quarter of 2000. Second, in May 2000 the oil price rose markedly again to an average of \in 30.4 per barrel, on account of both a rise in the world market price of oil and a further depreciation of the exchange rate of the euro. Exchange rate developments have also put upward pressure on import prices in general. For further information on the risks to price stability arising from developments in euro area import prices, see Box 3, which is entitled "Impact of import price developments on euro area consumer prices".

In addition to energy prices, processed food prices contributed, albeit marginally, to the fall in HICP inflation in April 2000. The yearon-year rate of increase in processed food prices fell from 1.0% in March to 0.9% in April, mainly as a result of developments in some food and alcoholic beverage prices.

By contrast, the annual rate of change in services and unprocessed food prices rose noticeably from March to April 2000 (see Chart 13). The annual rate of increase in services prices rose from 1.6% in March to 1.9% in April. This mainly reflects developments in package holiday prices and, to a lesser extent, passenger transport by air and accommodation services prices. While developments in these sub-indices tend to be

Chart 13 Breakdown of HICP inflation in the euro area by components

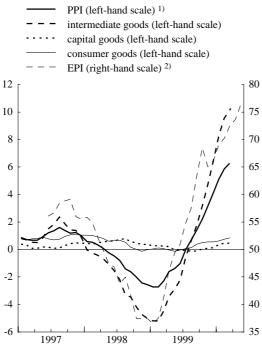

(annual percentage changes; monthly data)

volatile, the annual rate of increase in most passenger transport services price items has risen in recent months, possibly indicating a pass-through of the substantial rise in energy prices since early 1999. The year-on-year rate of change in unprocessed food prices rose from -0.5% in March 2000 to 0.2% in April 2000, a pattern which is seen in all unprocessed food price sub-items. Finally, the annual rate of increase in non-energy industrial goods prices remained unchanged from March to April 2000 at 0.6%. As a result of developments in services prices, the yearon-year increase in the HICP excluding seasonal food and energy rose from 1.1% in March to 1.2% in April 2000.

Chart 14

Producer prices and manufacturing input prices for the euro area (monthly data)

Sources: Eurostat and Reuters.

Producer prices reflect exchange rate and oil price developments

The annual rate of increase in euro area industrial producer prices rose from 5.9% in February 2000 to 6.3% in March 2000, thus continuing the steady upward trend in euro area producer prices, which reflects the strong increase in oil prices as well as the depreciation of the euro. As in previous months, the increase in March was mainly attributable to developments in intermediate goods prices. The annual rate of increase in intermediate goods prices rose from 9.6% in February to 10.2% in March, representing a new record high since the beginning of the 1990s. By contrast with the very high annual increase in intermediate goods prices, the annual rate of increase in capital and consumer goods prices has remained relatively low (at 0.5% and 0.8% respectively), even though they have followed a slight upward trend over recent months (see Chart 14). This provides some support for the view that higher intermediate goods prices are having an upward impact on final industrial goods prices further along the production chain.

Unit labour cost growth remained modest in 1999

The annual rate of increase in total hourly labour costs in the whole economy in the fourth guarter of 1999 has been revised upwards to 2.4% from a previous estimate of 2.2%. However, unit labour cost growth slowed to 0.4% year-on-year in the fourth quarter of 1999, from 0.9% in the third quarter, owing to a cyclical increase in productivity growth. Available information on wage bargaining suggests that negotiated wages in the euro area will increase moderately in 2000. For further information on the prospects for price and wage developments, see Box 4, which is entitled "A review of economic prospects for the euro area up to 2001", in the "Output, demand and labour market developments" section.

¹⁾ Industrial producer prices; annual percentage changes; excluding construction.

3 Output, demand and labour market developments

Available evidence suggests continued strong output growth in early 2000

For the euro area as a whole, the first estimate of real GDP growth for the first quarter of 2000 was scheduled for release by Eurostat after the cut-off date for this issue of the ECB Monthly Bulletin. However, available national data suggest that output growth continued in the first quarter, albeit at a slightly slower pace than that recorded in the latter part of 1999. Quarter-on-quarter growth in real GDP in the final quarter of 1999 is currently estimated to have been 0.8%, following an increase of 1.0% in the previous quarter (see Table 5). Output growth in the second half of last year was thus around 1/4 percentage point stronger (quarter-on-quarter) than in the first half of the year. This higher rate of growth was largely attributable to the improvement in net exports, while the other main component of expenditure which supported growth was private consumption. Owing to the stronger performance in the second half of 1999, real

GDP growth for the year as a whole stood at 2.4%, i.e. only slightly below the rate recorded in the previous year (at 2.7%).

Looking ahead, net exports appear to be set to continue to provide a stimulus to growth, owing to a combination of robust world growth and the lagged effect of the lower effective exchange rate of the euro. However, domestic demand is also expected to maintain or even increase its pace. The prospects for the euro area over the next one to two years are considered in further detail in Box 4.

Industrial production growth moderated in the first quarter of 2000

The latest estimates of industrial production in the euro area, which now extend to March 2000 and thus cover the first quarter of 2000, indicate a somewhat lower rate of growth than that observed in the autumn of last year. Excluding construction, industrial production

Box 4

A review of economic prospects for the euro area up to 2001

Over the past few months new and revised forecasts concerning the economic prospects for the euro area up to 2001 have been made available by the European Commission, the IMF and the OECD. To these can be added the latest results from the Consensus Economics forecasts and the Survey of Professional Forecasters compiled by the ECB. The currently available forecasts generally incorporate an upward revision of expected economic growth in 2000 and 2001, compared with the projections made at the end of last year and earlier this year (see Box 6 and Box 5 in the December 1999 and March 2000 issues of the ECB Monthly Bulletin respectively). At the same time, average consumer price inflation is now forecast to be higher this year and next year than previously anticipated. This box discusses the projections for euro area growth and inflation in more detail. It should be borne in mind that the forecasts referred to in this box are "central projections" surrounded by a certain degree of uncertainty. Moreover, they have been prepared and finalised at specific points in time, and they are conditional upon the precise assumptions made, for example, for interest rates and exchange rates. This applies both to the starting values prevailing at the time of preparing the respective forecasts results are derived on the assumption of rising short-term interest rates and of an euro exchange rate higher than recent market values. Oil price assumptions used also vary greatly between forecasts.

1) Inflation forecast based on HICP.

2) Inflation forecast based on the private consumption deflator.

3) Inflation forecast based on CPI (excluding data for Luxembourg, which are unavailable).

Real GDP growth forecast to be above 3% in 2000 and 2001

The currently available forecasts point to a broad consensus that real GDP growth in the euro area will be well above 3% in 2000 and still somewhat above 3% in 2001 (see the table above), rather than slightly below 3%, as was expected at the end of last year. On average, forecasts have been revised upwards by around ¹/₂ percentage point since then. With regard to the pattern of growth over the forecast period, the projections imply continued expansion, following the strengthening of growth in the second half of 1999.

The improved outlook for euro area growth emerging from the available forecasts can be seen as reflecting favourable conditions on both the domestic and the external side. First, in broad terms, the prospects for sustained strong growth in domestic demand are supported by the fact that confidence indicators are currently at their record highs and that credit growth has remained strong. Profitability can be expected to benefit from the current upturn as wage growth is expected to remain relatively moderate, while capacity utilisation rates will increase. Consistent with this, household incomes would benefit from ongoing strong employment growth and from increased non-wage incomes related to higher profitability. These factors should underpin

growth in private consumption and investment over the forecast horizon. Second, the stronger expansion of the global economy than was previously expected, combined with the low level of the euro's effective exchange rate in recent months, should contribute to rapid growth in exports.

The uncertainties surrounding the projections for real GDP growth in the euro area are seen by most international forecasters as coming mainly from the external environment. The biggest downside risk to growth still appears to be linked to the possibility of a pronounced slowdown in the US economy and the ensuing negative effects on the growth of the world economy. This risk might be considered as being mitigated by the possibility that growth in other areas of the world could turn out to be stronger than currently expected. More generally, some uncertainty about the external demand effects of world growth on euro area growth is related to forthcoming developments in the exchange rate of the euro in relation to the specific assumptions in the respective forecasts. On the domestic side, the latest forecasts tend to point to upside risks to growth.

Consumer price inflation forecast to be close to 2% in 2000 and 2001

According to the forecasts currently available, euro area inflation in 2000 and 2001 will be higher than expected at the end of last year. More specifically, following the low out-turn in 1999 of just above 1%, consumer prices are now expected to increase by close to 2% on average in each of the two forecast years (see the table above), compared with the rate of increase of around 1.5% projected at the end of last year. Part of the expected rise in inflation in 2000 is attributable to developments in oil prices in recent months. However, inflation excluding energy prices is also expected to rise steadily throughout the forecast period, essentially reflecting increasing demand pressures.

The pattern of overall consumer price inflation in 2000 and 2001 emerging from the available forecasts reflects both external and domestic influences. In the past few months import prices have accelerated rapidly on account of increasing oil prices and a depreciating exchange rate of the euro and they are expected to put further upward pressure on consumer prices as importers gradually pass through these effects. There is a certain degree of uncertainty in the forecasts for consumer price inflation related to the behaviour of oil prices and the exchange rate of the euro. In recent weeks oil prices are likely to have been stronger than had been assumed in many of the published forecasts, and the euro's exchange rate has been somewhat lower, despite its appreciation in late May and early June. If maintained, these factors will result in further upward pressures on consumer prices of downward pressure on consumer prices, but the strength of these effects is generally difficult to assess in quantitative terms.

In the context of the prospects for strong economic growth in the euro area, the more lasting effects of higher import price inflation on the rate of increase in consumer prices come via domestic factors. Reflecting the outcome of recent negotiations, currently available forecasts expect wages to grow relatively moderately over most of the forecast period up to 2001. Together with planned reductions in social security contributions and strong cyclical growth in productivity, this should result in modest increases in unit labour costs, particularly in 2000. Under these conditions, the forecasts imply that the main upward pressure on consumer prices will come from firms raising or restoring profit margins as a result of tighter demand conditions or higher cost pressures from import prices.

Overall, the consensus view regarding the economic prospects for the euro area in 2000 and 2001 emerging from currently available forecasts is that of strong economic growth in an environment in which inflation is expected to be close to 2%. However, it is important to recall that the forecast results are mostly derived on the assumption of a rise in short-term interest rates compared with the levels prevailing at the time of preparing the respective forecasts and of an euro exchange rate higher than current market values. Without these assumptions, forecasts for inflation would most likely have been higher.

Reflecting the strong economic growth and expectations of moderate wage growth anticipated by most forecasts, employment growth in 2000 and 2001 is mostly projected to remain strong and the unemployment rate to fall further over the two forecast years. The government budget deficit ratio is generally expected to decline slightly over the forecast period. However, the forecasts also imply that at the end of the period the unemployment rate will still be higher than at the beginning of the 1990s and that the fiscal stance is expansionary. Hence, while the outlook for the euro area economy is indeed favourable, the available forecasts point to a need for further efforts, notably in the area of structural reforms and fiscal consolidation. If accompanied by appropriate policies, this favourable outlook could extend into a period of sustained strong growth and stable prices.

is estimated to have risen by 1.1% in the first quarter of this year, compared with a quarter-on-quarter increase of 1.5% in the fourth quarter of 1999 (see Table 6). Manufacturing production also rose by just over 1% in the first quarter of 2000. There has thus been a gradual slowdown in the rate of increase in manufacturing production since late 1999.

Underlying developments total in manufacturing production, there has been divergence among the main some components. In particular, while production in the capital goods sectors is estimated to have increased in the first guarter of 2000 by 2.3%, production in the intermediate and consumer goods sectors has risen by 1.1% and 0.3% respectively. In the non-durable

goods sector production has declined by 2.2%. While there may be further revisions, the latest data appear to be broadly consistent with the pattern of recent increases in activity in the industrial sector over the past few months.

Further increase in industrial and consumer confidence

Both industrial and consumer confidence have risen to record high levels over the past few months (see Table 7). Industrial confidence has increased significantly from below its long-term average at the start of 1999 to reach a level in May 2000 equal to that seen in mid-1989, the highest level recorded since the start of the series in 1985. The further

1) Percentage changes compared with the previous period.

2) Percentage balances; data shown are calculated as deviations from the average over the period since January 1985.

3) Data are collected in January, April, July and October of each year. The quarterly figures shown are the average of two successive surveys, i.e. the surveys conducted at the beginning of the quarter in question and at the beginning of the following quarter. Annual data are quarterly averages.

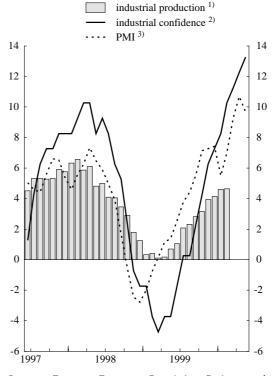

increase in industrial confidence in May 2000 was broadly based, being reflected in all three components (i.e. a more positive assessment of order books and production expectations and a decline in stocks of finished products).

The strong recovery evident in industrial confidence has also been reflected in the results of the Purchasing Managers' Index (PMI) for the euro area manufacturing sector. In May 2000 the PMI fell only slightly (to 59.7), after reaching a record high in the previous month. With the exception of suppliers' delivery times, which lengthened slightly for the fourth consecutive month, all other components (i.e. changes in output, new orders, employment and stocks of purchased goods) fell back somewhat. However, given that the PMI remains well above 50 (the value at which no change in the variable is signalled), these latest results point to further industrial production growth (see Chart 15).

Consumer confidence also rose in May 2000 to a new record high level, after having remained unchanged for the previous three consecutive months. Movements in the components of the overall consumer confidence indicator partly offset one another; those relating to the financial situation of households and the general

economic situation over the past 12 months, taken together, were slightly more positive, as was the willingness to make major purchases at present, while those relating to the assessment of the financial situation and the general economic situation over the next 12 months, combined, were slightly less positive.

Slower rate of growth in retail sales

Since the May issue of the ECB Monthly Bulletin, Eurostat has released data on retail trade turnover in the euro area for February and March 2000. According to the latest information, total retail trade rose by 1.6% in the first guarter of 2000 compared with the first quarter of 1999, a lower rate of growth than in the previous quarter (at 3.1%). In the latest three-month period the rate of increase in sales of food, beverages and tobacco continued to outstrip that of nonfood products (see Chart 16). The former is estimated to have risen by 2.8%, compared with a decline of 0.1% in the latter. The latest data should, however, be treated with some caution. The fall in retail sales recorded in March is likely to be at least partly attributable to the late timing of Easter this year. Moreover, it should also be noted that the latest estimates of area-wide retail sales are based on a limited set of data at the national level (covering only around 70% of retail trade in the euro area).

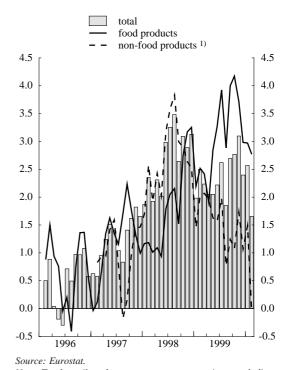

While the rate of growth in retail sales trade appears to have been lower in recent months, retail confidence has improved, according to the data released by the European Commission. Although volatile, both the assessment of the present business situation and production expectations have risen markedly since mid-1999, and there has also been a modest reduction in the volume of stocks.

A further indication of recent developments in consumption in the euro area is given by passenger car registrations (see the data presented in Table 5.2 in the "Euro area

Chart 16

Retail sales in the euro area

(annual percentage changes; three-month centred moving averages)

1) Owing to the unavailability of some national components, the series only starts from January 1996.

statistics" section of the ECB Monthly Bulletin). Data up to April 2000 indicate some recovery since last year, with the average rate of increase in the latest three-month period, at 3.5%, significantly above that recorded at the end of last year.

Overall, the pace of growth in economic activity in the euro area in the early part of 2000 appears to have been broadly sustained. A further increase has been recorded in production in the industrial sector and both business and consumer confidence have been maintained at high levels. Taken together, the latest available evidence suggests a continuation of the present economic expansion, supported by both domestic and external demand.

Preliminary indications of slightly higher employment growth

Employment figures in the euro area were revised upwards slightly in the last quarter of 1999 owing to a small revision of national components. Quarter-on-quarter employment growth is now estimated to have stood at 0.4% in the fourth guarter of 1999, compared with the previous estimate of 0.3%. This revision reflects an increase in the pace of net job creation in the last quarter of 1999, compared with the previous two quarters (see Table 8). Furthermore, preliminary estimates based on national data already available suggest a similar quarterly rate of growth in the first quarter of 2000. This appears to be consistent with a lagged effect of the strengthening of economic activity on employment growth and lends support to the positive employment outlook for the current year.

At the sectoral level, a recent Eurostat release for the first quarter of 2000 shows 0.1% growth in industry excluding construction, confirming the signs of improvement in total industry observed in the last quarter of 1999. The improvement in the fourth quarter is largely explained by a recovery in the manufacturing sector, together with a continuing positive contribution from the construction sector. In the last quarter of 1999 net job creation in the manufacturing sector was slightly positive for the first time that year. At the same time, employment in construction grew by 0.5%, i.e. slightly below the rate recorded in the previous quarter. According to available national accounts data, in the fourth quarter of 1999 the services sector is estimated to have created as many net jobs, in annual terms, as in the previous quarter.

Favourable employment expectations in industry and services

Employment expectations as seen in the European Commission Business Surveys support the overall positive outlook for employment developments in the first half of 2000. Across all sectors for which they are available, employment expectations were above their historical average in the second half of 1999 and have further increased since then. In the manufacturing sector, where employment expectations have shown some leading indicator properties vis-à-vis actual employment, they have improved continuously since the turning-point in mid-1999 (see Chart 17). In May 2000 employment expectations in the construction sector also reached a level well above their average for the 1990s. Finally, employment expectations for retail trade up to May 2000 compared positively with those of previous months (see Chart 18). Similarly, results for the first

quarter of 2000 from the Purchasing Managers' Survey also suggest a favourable outlook for employment in the services sector.

It is worth noting that the strengthening of actual employment growth and the favourable employment expectations described above occur against a background of sustained growth in the labour force. Female participation rates have continued to rise in line with a longer-term upward trend, while male participation rates have also substantially increased over the past few years, reversing an earlier trend decline. (For a more detailed analysis, see Box 5.)

The unemployment rate continued to fall in April 2000

In parallel with employment growth, unemployment has continued to decline (see Chart 19). In April 2000 the standardised rate of unemployment in the euro area stood at 9.2%, i.e. 0.1 percentage point below the rate recorded in March 2000 (see Table 9). The decline in the unemployment rate for the euro area has continued at a regular pace since the beginning of the year. This continuous downward trend in unemployment also points to an improvement in labour market conditions in the early part of 2000, which is expected to continue over the coming months.

The breakdown by age shows that the unemployment rate of both those under 25 years of age and those over 25 years fell in

2) In 1999 this category represented 76.9% of total unemployment.

April 2000. The unemployment rate of the former stood at 17.2% in April 2000, which corresponds to a fall of 0.3 percentage point compared with the previous month and 0.6 percentage point since the beginning of the year. This recent development contrasts with the relative slowdown in the decline of unemployment recorded between November

Chart 19

Unemployment in the euro area

(monthly data; seasonally adjusted)

group. The unemployment rate for those over 25 years of age stood at 8.2% in April 2000, almost 0.1 percentage point below the rate recorded in March 2000 and a fall of 0.2 percentage point since the beginning of the year. Despite a weaker improvement in April 2000, which was not noticeable as a result of rounding effects, the unemployment rate for those over 25 years of age continues to be on a slightly downward trend. At the national level, unemployment has declined in almost all euro area countries, especially in those in which the rate of unemployment has been highest.

1999 and February 2000 for the same age

In summary, the overall labour market outlook for the year 2000 appears to be positive for the euro area, with a continuously declining unemployment rate and improving employment prospects, together with a growing labour force. The moderate negotiated wage increases for this year should contribute towards supporting these favourable developments, as long as actual wage developments remain in line with wage settlements. In the longer term, sustained efforts towards achieving structural reforms and appropriate wage developments will be two key factors in consolidating the gains in employment and in continuing to reduce unemployment.

Box 5 Labour force developments in the euro area ¹

According to the recently released Eurostat Labour Force Survey, which covers all European Union Member States, labour force growth in the euro area is estimated to have been 0.8% in 1999. This is the same figure, as that for labour force growth on average in recent years, i.e. 1996-99, and it is expected to continue to grow at a similar rate this year.

In order to put labour force growth and its determinants in the relevant analytical context, the top part of the table shows developments in the labour force in the euro area as determined by working-age population growth and the participation rate, on the one hand, and as reflected in developments in employment and unemployment, on the other. Three recent periods have been considered: 1986-90, 1992-95 and 1996-99. 1991 has been excluded on account of a break in the series owing to German unification. While the first and third periods were ones of economic expansion, the second was characterised by a recession. Over the whole period population growth, which can be considered as exogenous, was on a downward trend. The participation rate fell slightly in the early 1990s; however, it shows an upward trend for the period as a whole and has been positively related to the economic situation. In response to these driving forces, labour force growth slowed down to 0.1% on average between 1992 and 1995, after having recorded an average rate of 1.3% in the previous period, only to resume its growth again in recent years. At the same time, from the point of view of labour force components, i.e. employment and unemployment, they moved in opposite directions over the three periods. Employment growth, in response to economic strengthening, absorbed the increasing labour force in the expansionary periods, leading to unemployment reductions. During the recession the fall in employment, together with the slight increase in the labour force, implied a significant increase in unemployment.

There is evidence that labour force growth responds to the situation of the economy through the participation rate. The argument is that strong economic growth leads to a fall in the unemployment rate, which gives a positive signal to those not participating in the labour market, i.e. not working and not seeking a job, while an economic slowdown tends to discourage potential workers from participating at all. However, changes in the population also play a role, both in terms of growth and composition. Furthermore, it is also important to look at developments by gender, owing to the different trends in participation rates.

Changes in participation rates have dominated demographic changes in recent years

Changes in the labour force can be categorised according to two effects: effects of population growth, which take into consideration changes in population for a given participation rate, and those of changes in labour force participation, via changes in the activity rate for a given population. The results indicate that over the past few years (1996-99) the effect of changes in the participation rate has dominated the growth of the population, contributing by 0.6 and 0.2 percentage point respectively to the change in the labour force (see the table below). This contrasts with the end of the 1980s, when the two effects were more similar (i.e. a contribution of 0.8 and 0.5 percentage point respectively). Finally, during the period of recession, i.e. the first part of the 1990s, the small increase in the labour force was fully explained by population growth, which counterbalanced the slightly negative contribution from the fall in the participation rate.

Apart from population growth, in order to explain labour force developments it is also important to focus on changes in the composition of population. From 1986 to 1999 both changes in the composition of the population and changes in participation rates among age groups seem to have been relevant in terms of labour force developments. Middle age categories, which have the highest rates of participation, increased their

¹ Only data for Germany, France, Italy, Spain and the Netherlands are available for the reference period. These countries added up to 86% of the euro area labour force in 1999.

1) Contributions to labour force growth.

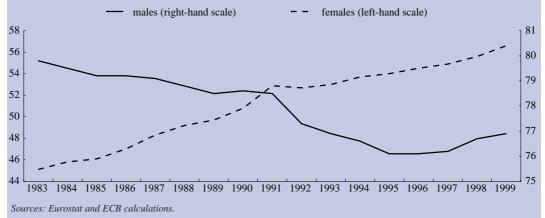

relative weight in the population. At the same time, all age categories experienced an increase in labour force participation, with the exception of the youngest and the oldest. One possibility for examining the importance of population composition in relation to changes in participation is to calculate the participation rate of the whole economy using 1986 population weights and the observed participation rates in 1999 using a breakdown by age and gender. The results indicate that the current participation rates alone cannot explain the increase in the labour force, although these again appear to be more important than changes in population. Moreover, the effect of participation rates is comparatively more significant in the second half of the 1990s than in the second half of the 1980s.

Male participation rates have increased over the past few years

The decomposition of labour force growth showing the effect of population growth and participation rate changes for a breakdown by gender reveals two different forms of behaviour. On the one hand, the female labour force has grown over all three periods, basically as a result of the effect of growing participation rates, which contribute by between 0.7 and 2.0 percentage point to labour force growth, while population growth effects are much less significant. On the other hand, the male labour force grew in the previous 1986-90 period owing to population growth effects. However, as shown in the chart below, male participation behaviour in the recent past (1996-99) has changed and the increasing participation rate has mainly been responsible for the growth of the labour force. Indeed, since the early 1980s male participation had been decreasing constantly, falling more strongly during the recession, while in recent years it has started to increase

(rising by 0.2 percentage point on average). By contrast, female participation has increased throughout all three periods. The breakdown by gender and age group indicates that changes in male participation rates between the two expansionary periods are mainly identified in the youngest and oldest population groups, while the increase in female participation rates is broadly based among age groups in both periods, although it was less intense in the second period.

Participation rates by gender in the euro area (as a percentage of the total population by gender; annual data)

In summary, in terms of explaining labour force developments, changes in participation have been more significant in recent years than changes in population, by contrast with the end of the 1980s. In addition, although females continue to be the main contributors to the labour force increase, it is important to note that over the past few years males have gained some weight in explaining this increase, owing to a rise in male participation rates after some years of a continuous downward trend.

4 Fiscal developments

Budgetary balances improve further, however a pro-cyclical bias in fiscal policies is envisaged in 2000 and 2001

Government balances are expected to improve in 2000 and 2001, however at a slowmoving pace. According to the latest forecasts published by international organisations, the euro area deficit in 2000 is projected to be, on average, 1% of GDP, down from 1.2% in 1999 (see Table 10). A further marginal improvement is envisaged for 2001, although budgetary prospects in a number of countries are likely to worsen. The euro area primary surplus is forecast by the European Commission to remain stable at 3.1% of GDP over the period from 1999 to 2001. Budgetary projections are somewhat more optimistic than the targets set by Member States' updated stability programmes, as the cyclical upswing has been more buoyant than expected.

However, the outlook for improving overall balances masks a slight deterioration in underlying budgetary positions (see Chart 20). European Commission estimates suggest that the structural budget deficit will deteriorate from 0.7% in 1999 to 1.0% in 2001. This outlook would imply that no further fiscal consolidation at the aggregate level is expected over this period, in which only two countries envisage active fiscal tightening. Furthermore, the deterioration in the structural budget balance of the euro area indicates both a pause in the process of achieving budgetary positions close to balance or in surplus and a pro-cyclical loosening of the fiscal policy stance.

In 2000 and 2001 the revenues ratio is expected to fall by 1.5 percentage points from the historical high recorded in 1999 as a result of cuts in direct taxes and social security contribution rates in most euro area countries (see Chart 21, in which a reduction in expenditure as a percentage of GDP or an increase in the receipts ratio are depicted as a positive contribution to changes in the budget balance ratio). Expanding tax bases (owing to strong growth and institutional changes), increasing efficiency in tax collection and rising indirect taxes will partially compensate for the revenue loss arising from lower tax rates on households and corporations. Direct taxes and social security contributions are forecast to decrease as a percentage of GDP, while indirect taxes are

expected to remain practically stable. The timing, nature and size of tax reductions differ considerably across countries. Tax reforms, however, could result in unexpected revenue shortfalls and recent increases in receipts related to strong oil and asset prices may be transitory.

The ratio of total expenditure to GDP is forecast to decline in the euro area by nearly 2 percentage points in 2000 and 2001. A slow decline in the size of the debt and lower interest rates on refinanced obligations will make a positive contribution, albeit less than in previous years, towards reducing the aggregate expenditure ratio. Both current transfers to households (including unemployment-related outlays) and public consumption are forecast to decline significantly in respect of GDP. Achieving expenditure targets will require tighter control of public spending in the future, especially in the light of the 1999 expenditure overruns experienced in almost half of the area countries. euro Overruns were

concentrated in the social security sector and particularly in the provision of health care. The ability to control spending outside the central government has also proven to be difficult in some countries.

Improving budget balances in Member States together with planned tax and expenditure reforms are clearly a step in the right direction. However, against the background of the current upswing and the planned tax cuts, member countries are not putting enough emphasis on containing discretionary expenditure. This introduces a pro-cyclical bias into their fiscal policies. This bias is inconsistent with the policy framework of the Stability and Growth Pact, which calls for the automatic stabilisers to operate fully over the cycle. Moreover, it comes into conflict with the objective of achieving, as soon as possible, medium-term budgetary positions which are close to balance or in surplus, as laid down by the Stability and Growth Pact. There are also risks of countries achieving only the budgetary targets laid down in their updated stability programmes, instead of using the cyclical gains to improve on these targets. In this respect, it is worth reiterating the fact that the current opportunity to put public finances on a sounder footing should not be missed. Finally, in a number of countries announced fiscal policies will boost aggregate demand, thus increasing the risks of economic overheating and inflationary pressures.

Long-term challenges in public finances remain

In addressing impending challenges to public finances, fiscal policy strategies should take due account of the level of public debt and, more generally, the long-term sustainability of public finances before embarking on ambitious tax cutting measures. The public debt ratio is projected by the European Commission to decline at a slow pace in the euro area from 72% in 1999 to 68% by 2001. The ratio still remains high or even very high in a number of Member States. Moreover, recent reforms in social security systems are only now starting to address the challenges related to the ageing of the population.

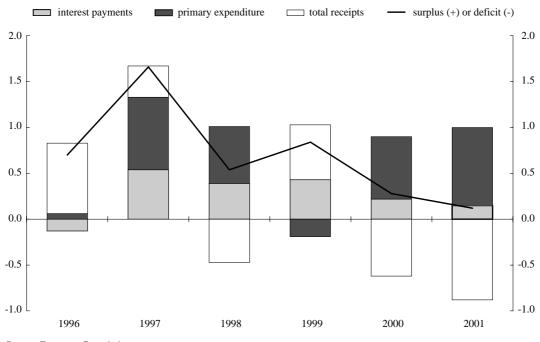

The need both to make further progress in fiscal consolidation and to strengthen the sustainability of public finances is closely linked to the issue of growth-enhancing fiscal structural reform, for the successful introduction of the latter can make a significant contribution to sounder public finances. The current structure and size of government sectors in the euro area is still regarded as having detrimental effects on competitiveness, economic dynamism and growth, and the announced plans will only mitigate some of these effects.

Growth-enhancing tax and expenditure reforms should be high on government agendas. With regard to taxation, high social security contributions, labour income taxes and marginal tax rates are detrimental

Chart 21

Annual changes in the average euro area budgetary position: contributions of receipts, primary expenditure and interest payments

Source: European Commission.

to work incentives, participation and employment rates, particularly - but not exclusively - at the lower end of the wage scale. The large fiscal burden together with various regulations is also seen as undermining entrepreneurial activity. In terms of public spending, reforms in transfer systems could help to finance tax reforms while encouraging labour force participation. Reductions in public employment could also create room for tax cuts, while at the same time reducing labour market bottlenecks and wage pressures in some countries. A re-prioritisation of existing public spending programmes from less productive to greater growth-enhancing items is also needed to boost both physical and human capital formation.

Such reforms have their greatest effect when a comprehensive rather than a piece-meal approach is followed. They mutually reinforce one another and create a virtuous circle of incentives promoting growth which, in turn, permits further fiscal consolidation and tax reductions. Structural reform in the public sector, including tax cuts, and fiscal consolidation are complementary objectives. If merely marginal changes were introduced in limited areas, this would give rise to the risk of the beneficial supply side and consolidation effects only being minimal.

Finally, the sequencing of structural fiscal reform is very important. Supply side effects of such reforms are likely to take some time before materialising and risks to fiscal consolidation could arise if countries expect tax cuts to finances themselves fully and immediately through higher growth. Therefore, tax reductions should be accompanied by sufficient compensatory expenditure restraints, particularly at the beginning of the reform process.

5 The global macroeconomic environment, exchange rates and the balance of payments

The strong global upswing continues

Since the March 2000 issue of the ECB Monthly Bulletin was published, the outlook for the global economy has continued to strengthen, as has the euro area's external demand. Developments in major industrialised countries as well as in emerging market economies suggest that the global economy is experiencing a strong upswing likely to carry over into 2001, albeit at a more moderate pace. With regard to the major non-euro area industrialised countries, the record US expansion continued unabated in the first quarter of 2000, although there are some early signs that output growth may moderate over the medium term. In the United Kingdom output growth remained robust in the first quarter driven mainly by buoyant consumer spending. In Japan output recorded slightly positive growth in 1999 and there are indications that the recovery may strengthen gradually in the course of 2000.

With regard to emerging market economies, Asian economies have showed the strongest growth supported by buoyant exports and rising domestic demand. In the largest EU accession countries the outlook is positive, although there are still concerns with regard to sizeable current account deficits in some countries. In Russia the short-term perspectives have improved, yet pending structural reforms are generating uncertainty as to whether the growth may be sustained. In Latin America economic activity is also recovering fully from last year's standstill, although recent volatility in domestic financial markets emphasises the fact that the recovery remains fragile.

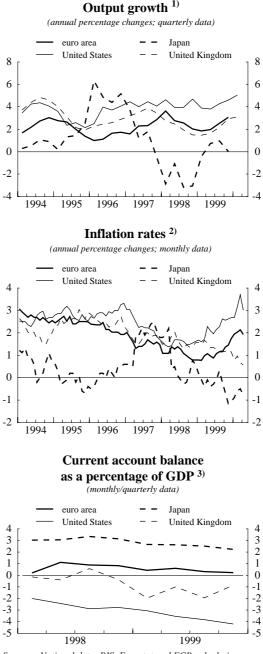

Global inflation has risen and inflationary risks have increased in the context of higher global demand and uncertainty about oil price developments. In the United States the economy continued to expand strongly as real GDP is estimated to have grown by 1.3% (quarter-on-quarter) in the first quarter of 2000. Personal consumption and business fixed investment expenditure contributed the most to GDP growth in the first quarter, while net exports and inventories made a negative contribution to growth. The remarkable strength of domestic demand during the present expansionary period has led to the widening of the current account deficit to 3.8% of GDP in 1999, from 2.5% in 1998. The external imbalance may widen further in 2000 as the trade deficit increased to USD 86.3 billion in the first quarter of the year compared with USD 51.0 billion in the same quarter a year ago.

Recent coincident and leading indicators provide mixed signals regarding the economy's medium-term outlook. Although growth in retail sales declined somewhat in April 2000, real personal consumption expenditure expanded at a robust rate of 5.5% (year-on-year) in that month, consumer confidence rebounded strongly in May, almost reaching its record high of January 2000, and industrial production recorded its largest monthly gain in almost two years in April 2000. By contrast, the composite index of leading indicators, as computed by the Conference Board, remained almost flat in April 2000 and business confidence weakened to some extent in May 2000, while new orders for durable goods and sales of new homes declined significantly in April. The strongest, yet still tentative, signal of a possible slowdown in economic activity came from unexpectedly weak employment growth in the non-farm business sector in May 2000 and a rise in the unemployment rate to 4.1%in May 2000, from 3.9% in April. Finally, inflation subsided somewhat in April 2000 mainly as a result of lower energy prices -CPI inflation fell from 3.8% (year-on-year) in March to 3.0% in April (see Chart 22).

On 16 May 2000 the Federal Open Market Committee (FOMC) raised its target for the federal funds rate by 50 basis points to 6.5%, stating that "increases in demand have remained in excess of even the rapid pace of

Chart 22

Main developments in major industrialised economies

Sources: National data, BIS, Eurostat and ECB calculations.

- Eurostat data are used for the euro area and the United Kingdom; for the United States and Japan national data are used.
- Data for the euro area up to 1995 are estimates for the HICP based on national CPI data; after 1995 HICP data are used.
- 3) ECB and Eurostat data are used for the euro area and the United Kingdom; for the United States and Japan national data are used. For the United States, United Kingdom and Japan figures refer to seasonally adjusted data for both GDP and the current account, for the euro area GDP data are seasonally adjusted, while the current account balance data are not seasonally adjusted.

productivity-driven gains in potential supply, exerting continued pressure on resources". Against the background of its long-term goals of price stability and sustainable economic growth, and in the light of the information available at the time of the meeting, the FOMC also communicated that the risks were weighted mainly towards conditions that may generate heightened inflation pressures in the foreseeable future.

In Japan the outlook still appears somewhat mixed. Real GDP contracted in the last quarter of 1999, bringing annual average growth to 0.3% for the whole of 1999. However, in the first months of 2000 encouraging economic indicators suggested that the economy is gradually recovering. In the first quarter of the year industrial production increased by 0.8% (quarter-onquarter), fuelled by higher domestic and external demand for investment goods, such as general and electrical machinery products. Given that the global economic outlook remains positive and business confidence in Japan is improving, as demonstrated by the results of the Tankan survey of March 2000, demand for investment goods is likely to help to sustain the recovery. The fiscal package approved late last year has also helped to boost manufacturing activity, raising public works contracts sharply in the first three months of the year. Nevertheless, caution is warranted when assessing the medium-term outlook, as private consumption growth, discernible despite some signs of improvement, remains a legitimate concern for the sustainability of the Japanese recovery.

Deflationary pressures in Japan as measured by the wholesale price index may have bottomed out after two years of steady decline. Against the background of signs of a recovery in domestic demand, the Bank of Japan is reassessing the conditions under which its I5-month-old "zero interest rate" policy might be abandoned.

In the United Kingdom real GDP expanded by 0.5% (quarter-on-quarter) in the first quarter of 2000 compared with a rise of 0.8%

in the previous quarter. The divergence between output trends in manufacturing and in the services sector re-emerged in early 2000. While the strength of the pound sterling against the euro adversely affected manufacturing output, strong domestic demand buoyed production in the services Robust consumer spending sector. supported by positive developments in disposable income, housing and financial asset prices - remained the mainstay of domestic demand. Business investment grew by 1.9% (quarter-on-quarter) in the first quarter of the year, led by growth of investment in the services sector which amounted to 2.7% (quarter-on-quarter).

The UK labour market tightened further. Unemployment continued to fall during the first quarter of 2000, as the employment rate and the number of new vacancies continued to increase. Inflation, as measured by the Retail Price Index excluding mortgage interest payments (RPIX), continued to stand below the official target of $2\frac{1}{2}$ %. In April 2000 RPIX inflation slowed to 1.9% (year-on-year) compared with 2.0% in March and 2.2% in the final quarter of 1999.

In the Asian emerging market economies, the recovery is continuing at a fast pace driven by buoyant exports and domestic demand. Export revenues are rising in particular in the electronic sector - benefiting South Korea, Singapore, Malaysia and Taiwan - and in the oil sector following the rise in crude oil prices - benefiting oil-producing countries such as Malaysia and Indonesia. The recovery in domestic demand is taking place in the context of accommodating macroeconomic policies, high current account surpluses and subdued inflation. Overall, the main concern regarding Asian emerging market economies is that the rapid recovery might lead to complacency and a slowdown in structural reforms, especially in the financial sector.

In the largest EU accession countries, output has continued to grow at a rapid pace. In Poland sustained investment and consumer demand have fuelled economic growth, while

Box 6

World trade, GDP and inflation outlook according to OECD, European Commission and IMF forecasts

Reflecting the positive developments in the global outlook, the OECD, the European Commission and the IMF have revised upwards their forecasts for world GDP. All three institutions expect world output to grow by between 4.0% and 4.3% this year, and to slow down to around 3.8% to 3.9% in 2001. The aforementioned institutions forecast that world trade growth will also accelerate to between 7.9% and 10.4% in 2000 and moderate to between 7.2% and 8.3% in 2001. Despite closing or already positive output gaps, they also forecast that inflation will remain moderate over the forecasting horizon (2000-01). The moderate global inflation reflects anticipated tightening of monetary policy as well as the assumption that both oil and non-oil commodity prices will not continue to rise significantly during the forecasting period.

All three institutions agree that most of the risks to the outlook remain unchanged from previous forecasting rounds but their balance may be changing, while a number of new risks appear to be arising. The bulk of the risks relate to a disorderly correction in equity markets in the United States resulting from the imbalances that have emerged during the long expansion of the US economy. To this the OECD adds two downside risks. One refers to a halt of the ongoing recovery in Japan arising from either a sharp appreciation of the yen or a stalling of structural reform. The second risk, at a global level, is related to the fact that the strength of the world expansion may lead to an overheating of the global economy.

OECD, European Commission and IMF forecasts

(annual percentage changes)

Sources: OECD, European Commission and IMF.

1) For the OECD the comparison is between May 2000 and December 1999 forecasts; for the EC it is between April 2000 and November 1999 forecasts; while for the IMF April 2000 forecasts are compared with those of October 1999.

the widening of the current account deficit remains the primary concern. In Hungary growth has accelerated since the second half of 1999, supported by strong export growth and an accommodating monetary policy. In the Czech Republic the economy is continuing to recover gradually, while prospects for a strengthening of demand have improved recently, mainly on account of the improved outlook for the euro area. In Russia, although the short-term prospects remain positive in terms of output, inflation and the current account, uncertainty about the pace of structural reforms could become the main stumbling block for growth in the medium term.

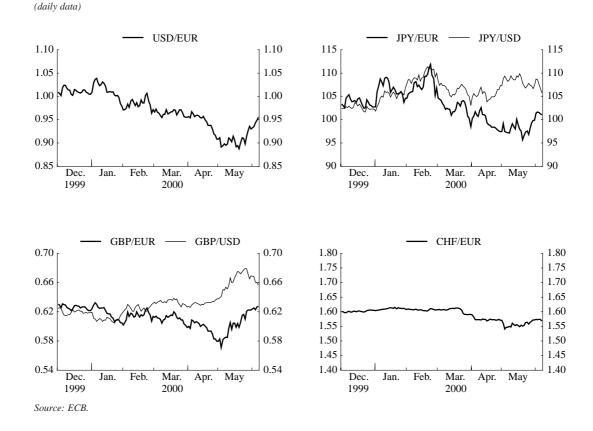

The overall economic outlook for Latin America remains positive and the region is expected to rebound strongly this year. Mexico and Brazil, in particular, continue to show robust growth, and Argentina is also recovering, albeit more slowly. Most of the smaller economies are also catching up with the major economies in the region. However, the region's recovery continues to be fragile as it depends to a large extent on external demand and capital inflows. This has been underlined by the recent volatility in domestic financial markets.

Chart 23

Patterns in exchange rates

The euro recovered from late May to early June

Overall, the period from early May to 7 June 2000 was characterised by a rebound of the euro against all major currencies. The euro initially began to appreciate against the pound sterling in early May, while, from mid-May onwards, it also strengthened against the US dollar and the Japanese yen (see Chart 23). The latter strengthening of the be predominantly euro appeared to attributable to a positive change in general market sentiment towards the euro. This change in sentiment has been mostly associated with a wider realisation that the external value of the euro might be out of line with improved economic developments and prospects in the euro area. In nominal effective terms, the euro appreciated by 3.4%

ECB Monthly Bulletin • June 2000

from 11 May to 7 June 2000, reaching levels seen in late March 2000. Nevertheless, in spite of the recent strengthening of the euro, the impact of its earlier sizeable depreciation remains a cause for concern in the context of the medium-term inflation outlook.

Considering developments in some more detail, the euro depreciated slightly against the US dollar in the aftermath of the decision by the US Federal Reserve System to raise the policy rates by 50 basis points on 16 May 2000, before strengthening during the second half of May for the reasons mentioned above. By late May the appreciation of the euro was further supported by data releases in the United States which were interpreted as early signs that the US expansion might moderate its pace, indicating that the growth differential between the euro area and the United States could narrow over the medium term. The significant volatility in US equity markets, particularly in the technology sector, might also have contributed to the euro's rebound. On 7 June 2000 the euro stood at USD 0.955.

Turning to the Japanese yen, during the first weeks of May 2000 it remained mostly unchanged against the euro, but depreciated during the last weeks of May and the first week of June. Overall the strengthening of the euro against the yen reflected the generally positive market perception in respect of the euro. The strong decline in the Nikkei 225 index as well as the still somewhat mixed Japanese economic outlook, as depicted in May data releases, could be seen as additional contributory factors. The yen remained in a relatively narrow range vis-à-vis the US dollar during the second half of May. In early June, however, it strengthened against the dollar following the announcement of weaker than expected data in the United States. On 7 June the euro stood at JPY 101.0.

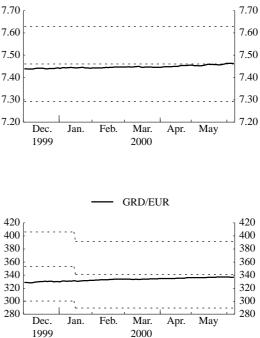

Throughout May and early June the pound sterling first depreciated and later on broadly stabilised against both the euro and the US dollar, after having posted record high levels in nominal effective terms in April. The depreciation of the pound sterling occurred in parallel to the decision taken by the Bank of England to leave interest rates unchanged at its meeting on 5 May 2000 amid a subdued inflation outlook. At the meeting of 7 June 2000, the policy rates were also left unchanged. On 7 June the euro was quoted at GBP 0.628.

Within ERM II, in the course of May and early June 2000, the Greek drachma fluctuated within a narrow range vis-à-vis the euro. On 7 June the drachma was quoted around 1.2% above its central parity of GRD 341 vis-à-vis the euro. The Danish krone remained virtually unchanged at around DKK 7.46 against the euro (see Chart 24).

After having appreciated strongly against the euro in March and April 2000, the Swiss franc first stabilised and thereafter slightly

Note: The horizontal lines indicate the central parities (DKK 7.46; GRD 340.75, with the latter effective from 17 January 2000) and the respective fluctuation bands ($\pm 2.25\%$ for DKK and $\pm 15\%$ for GRD).

Chart 25

Nominal and real effective exchange rates ¹⁾

(monthly/quarterly averages; index: 1999 Q1 = 100)

Source: ECB.

 Data are ECB calculations (see the article in the April 2000 issue of the ECB Monthly Bulletin). An upward movement of the index represents an appreciation of the euro. The latest observations are for May 2000 and for the ULCMbased REER for Q1 2000.

depreciated against the euro in May and in early June. In May 2000 the euro also appreciated against the Swedish krona mostly as a result of high volatility in the Swedish stock markets.

The recovery of the euro against all major currencies from late May to early June 2000 was also reflected in the nominal effective exchange rate index, which summarises the evolution of the external value of the euro against the currencies of the 13 major trading partners of the euro area. The euro appreciated in effective terms by almost 3.4% between 11 May and 7 June. On 7 June the euro stood at around 12.4% below the level recorded in the first quarter of 1999, while the nominal effective depreciation of the euro amounted to 1.5% when compared with the first quarter of 2000. Movements in the CPI, PPI and ULCM-deflated effective exchange rate indices continued to track fairly closely those of the nominal index, so that in May 2000 these indicators were pointing to a real effective depreciation of a similar size to the one suggested by the nominal index (see Chart 25).

Current account continued to decline during the first quarter of 2000

During the first quarter of 2000 the current account of the euro area recorded a deficit of $\in 1.2$ billion, compared with a surplus of $\in 6.4$ billion for the same period last year (see Table 11). The greater part of this decline is explained by the fall in the goods surplus (from $\in 21.5$ billion to $\in 15.3$ billion). Increases in the deficits on services and current transfers, only partially offset by a smaller deficit on the income account, also contributed to the decline in the current account over this period.

When compared with the same period last year, the value of exports of goods grew by \in 39.3 billion (or around 22%) in the first quarter of 2000, while imports increased by \in 45.5 billion (or around 29%) over the same period. According to the most recent information, the rise in export values seems primarily to reflect strong growth in export volumes owing to robust foreign demand and improvements in euro area competitiveness. By contrast, the value of imports has risen primarily due to the strong increase in import prices – by over 20% in the 12-month period up to February 2000 – owing to higher oil prices and the decline in the euro.

The current account surplus declined to $\in 3.0$ billion in March 2000 (from $\in 6.4$ billion in the corresponding month of 1999). Half of the decline was a result of a fall in the goods surplus (to $\in 8.1$ billion, from $\in 9.8$ billion in 1999), but the deficit on current transfers also increased significantly, while the balance for services registered a slight deterioration. By contrast, the deficit on the income account decreased by $\in 1.0$ billion.

Large takeover operation dominates financial flows figures in the first quarter

In the financial account the acquisition of a euro area company by a non-resident firm, which was settled through an exchange of shares and had already had an impact on

²⁾ Unit Labour Costs in Manufacturing.

February figures, also dominated direct and portfolio equity investment flows in March 2000. To some extent as a result of this takeover operation, direct investment in the euro area in that month (\in 35.4 billion) more than compensated for direct investment abroad by euro area residents (\in 33.0 billion), while there were substantial net equity outflows (\in 46.0 billion), resulting in net portfolio investment outflows of \in 24.7 billion.

Combined net direct and portfolio investment outflows amounted to \in 31.7 billion in the

first quarter of 2000, lower than in the first quarter of 1999. This was largely attributable to substantial net inflows in money market instruments, which reached \in 22.6 billion in the first quarter of 2000, the highest quarterly figure yet reported for the euro area.

In the first quarter of 2000 direct investment in the euro area reached \in 206.9 billion, i.e. almost three times the amount of total inflows for 1999 as a whole. This was to a large extent related to the sizeable takeover operation referred to above. However, even

 The rate for main refinancing operations is the rate applicable to fixed rate tenders. Changes in the rate are effective from the date of settlement of the first main refinancing operation following announcement of the change. Dates of settlement and amounts are shown below in Table 1.3.
 On 22 December 1998 the ECB announced that, as an exceptional measure between 4 and 21 January 1999, a narrow corridor of 50 basis points would be applied between the interest rates for the marginal lending facility and the deposit facility, aimed at facilitating the transition to the new regime by market participants.

 Liabilities vis-à-vis other credit institutions subject to the ESCB's minimum reserve system, the ECB and participating national central banks, are excluded from the reserve base. If a credit institution cannot provide evidence of the amount of its issues of debt securities with a maturity of up to two years and of money market paper held by the institutions mentioned above, it may deduct a certain percentage of these liabilities from its reserve base. This percentage was 10% for calculating the reserve base until November 1999, and 30% thereafter.

2) Maintenance periods start on the 24th of the month and run to the 23rd of the following month; the required reserve is calculated from the reserve base as at the end of the preceding month.

2. Reserve maintenance ¹⁾

1) This table contains full data for completed maintenance periods and required reserves for the current maintenance period.

2) The amount of reserve requirement of each individual credit institution is first calculated by applying the reserve ratio for the corresponding categories of liabilities to the eligible liabilities, using the balance sheet data as at the end of each calendar month; subsequently, each credit institution deducts from this figure a lump-sum allowance of EUR 100,000. The resulting reserve requirements are then aggregated at the euro area level.

figure a lump-sum allowance of EUR 100,000. The resulting reserve requirements are then aggregated at the euro area level.
Aggregate average daily holdings of credit institutions required to hold a positive amount of reserves on their reserve accounts over the maintenance period.
Average actual reserve holdings over the maintenance period in excess of the required reserves, computed on the basis of those credit institutions that have fulfilled the reserve requirement.

5) Average shortfalls of actual reserve holdings from required reserves over the maintenance period, computed on the basis of those credit institutions that have not fulfilled the reserve requirement.

6) This rate equals the average, over the maintenance period, of the ECB's rate (weighted according to the number of calendar days) on the Eurosystem's main refinancing operations (see Table 1.3).

1) The banking system's liquidity position is defined as the current account holdings in euro of credit institutions in the euro area with the Eurosystem.

Amounts are derived from the consolidated financial statement of the Eurosystem.
Includes monetary policy operations initiated by national central banks in Stage Two and outstanding at the start of Stage Three (excluding outright operations and the issuance of debt certificates).

3) Remaining items in the consolidated financial statement of the Eurosystem.

Figure 10 the difference between the sum of liquidity-providing factors (items 1 to 5) and the sum of liquidity-absorbing factors (items 6 to 10).
 Calculated as the sum of the deposit facility (item 6), banknotes in circulation (item 8) and credit institutions' current account holdings (item 11).

2 Monetary developments in the euro area

1) The ECB was established on 1 June 1998. The data shown for the Eurosystem relate to the ECB (as from June 1998) and the national central banks of Member States in the euro area.

2) From January 1999 including temporary gross positions of the Eurosystem with the national central banks of Member States not participating in the euro area related to the operation of the TARGET system. These positions amounted to approximately EUR 46 billion at end-January 2000, EUR 40 billion at end-February, EUR 51 billion at end-March, EUR 47 billion at end-April and EUR 53 billion at end-May. For positions at end-months in 1999 see the corresponding footnote in the February 2000 issue.

1) Monetary aggregates comprise monetary liabilities of MFIs and central government (Post Office, Treasury) vis-à-vis non-MFI euro area residents excluding

Taking the December 1998 outstanding level (not seasonally adjusted) as 100, the index shows the cumulative product of changes from that date calculated from flows as described in footnote 4. The percentage change in the index between any two dates corresponds to the change in the aggregate excluding such reclassifications, etc.

Credit comprises loans and holdings of securities other than shares issued by euro area residents.
 Calculated from monthly differences in levels adjusted for reclassifications, other revaluations, exchange rate variations and any other changes which do not arise from transactions. For the calculation of growth rates, see the technical notes.

Outstanding amounts are not adjusted for reclassifications, other revaluations or exchange rate variations. Data are partially estimated.
New reporting rules as from January 1999 caused significant breaks in the first quarter of 1999.
The term "banks" is used in this table to indicate institutions of a similar type to MFIs resident outside the euro area.
Deposits placed by MFIs with banks located outside the euro area are included.

Euro area government bond yields

(monthly)

10-year government bond yields (monthly)

Sources: Reuters, ECB, Federal Reserve and Bank of Japan.

¹⁾ To December 1998, 2, 3, 5 and 7-year euro area yields are end-of-period values and 10-year yields are period averages. Thereafter, all yields are

period averages. To December 1998, euro area yields are calculated on the basis of harmonised national government bond yields weighted by GDP. Thereafter, the weights are the nominal outstanding amounts of government bonds in each maturity band. 2)

Lending interest rates

Deposit interest rates

(monthly)

Source: ECB.

These euro area retail bank interest rates should be used with caution and for statistical purposes only, primarily to analyse their development over time rather than their level. They are calculated as the weighted average of national interest rates provided by the national central banks. The national rates represent those rates that are currently available from national sources and which are judged to fit the standard categories. These national rates have been aggregated to derive information for the euro area, in some cases relying on proxies and working assumptions due to the heterogeneity observed in the national financial instruments across MU Member States. Furthermore, the national interest rates are not harmonised in terms of their coverage (new business and/or outstanding amounts), the nature of the data (nominal or effective) or the compilation method. The country weights for the euro area retail bank interest rates are derived from MFI balance sheet statistics or close proxies. The weights reflect the country-specific proportions of the relevant instruments within the euro area, measured as outstanding amounts. The weights are adjusted monthly, so that interest rates and weights always refer to the same month.

 Brent Blend (for one-month forward delivery). To December 1998, in ECU; from January 1999, in euro.
 Based mainly on the ESA 95; data to end-1998 are based on national deflators in domestic currency.
 Deflators for exports and imports refer to goods and services and include cross-border trade within the euro area.

Real economy indicators in the euro area 5

Sources: ECB calculations based on Eurostat data (columns 1 to 6 and 18), Eurostat (columns 7 to 10, 14 to 17) and ECB calculations based on national data (columns 11 to 13 and 19).

(columns 11 to 13 and 19).
1) Data for employment are based on the ESA 95. Due to differences in coverage, quarterly data are not fully consistent with annual data. Data for unemployment follow ILO recommendations.
2) Adult, 25 years and over; youth, below 25 years; expressed as a percentage of the labour force for the relevant age group.
3) Hourly labour costs for the whole economy, excluding the agriculture, public administration, education and health sectors. Owing to differences in coverage,

components are not consistent with the total.

Source: Eurostat; the commodity breakdown is in accordance with the SITC Rev. 3.
1) Owing to differences in definitions, coverage and time of recording, trade data (as compiled by Eurostat) are not fully comparable with the goods item in the balance of payments statistics compiled by the ECB (Table 8.2). Part of the difference arises from the inclusion of insurance and freight services in the recording of goods imported, which accounted for about 3.8% of the value of imports (c.i.f.) in 1998.
2) ECB calculations based on Eurostat data.

Source: Eurostat: the commodity breakdown is in accordance with the SITC Rev. 3.
Owing to differences in definitions, coverage and time of recording, trade data (as compiled by Eurostat) are not fully comparable with the goods item in the balance of payments statistics compiled by the ECB (Table 8.1). Part of the difference arises from the inclusion of insurance and freight services in the recording of goods imported, which accounted for about 3.8% of the value of imports (c.i.f.) in 1998.

ECB Monthly Bulletin • June 2000

Source: ECB.

1) ECB calculations; based on weighted averages of bilateral euro exchange rates. Weights are based on 1995-97 manufactured goods trade with the trading partners and capture third-market effects. The narrow group is composed of the countries whose currencies are shown in the table. In addition, the broad group includes the following countries: Algeria, Argentina, Brazil, China, Croatia, Cyprus, the Czech Republic, Estonia, Hungary, India, Indonesia, Israel, Malaysia, Mexico, Morocco, New Zeland, the Philippines, Poland, Romania, Russia, Slovakia, Slovenia, South Africa, Taiwan, Thailand and Turkey. Real rates are calculated using consumer prices (CPI), producer prices in manufacturing (PPI) and unit labour costs in manufacturing (ULCM). Where deflators are not yet available, estimates are used.
To December 1998, rates for the ECU (source BIS); from January 1999, rates for the euro.

As the ECB does not provide official reference rates for these currencies, indicative rates are shown. 3)

4) The table shows the percentage change in the latest monthly observation vis-à-vis the previous month, and vis-à-vis the same month of the previous year. A positive change denotes an appreciation of the euro.

Technical notes

Relating to Table 2.4

Seasonal adjustment of the euro area monetary aggregates

Multiplicative versions of X-12-ARIMA (version 0.2.2¹) and TRAMO/SEATS² (beta version, July 1998) are used. For technical reasons, the results of X-12-ARIMA are published as the official figures. Seasonal adjustment for monetary aggregates includes a day-of-the-week adjustment for some components of M2. The seasonal adjustment of M3 is carried out indirectly by aggregating the seasonally adjusted series of M1, M2 less M1, and M3 less M2 to fulfil the additivity constraint.

Seasonal factors are estimated for the index of adjusted stocks (Table 2.4.1). They are then applied to the levels expressed in EUR billions and to the adjustments due to reclassifications, other revaluations, etc., yielding seasonally adjusted values for the levels, the adjustments, and thus for the flows.

Calculation of growth rates

Growth rates may be calculated (a) from flows, or (b) from the index of adjusted stocks.

If F_t represents the flow in month t, L_t the level outstanding at the end of month t, X_t the rate of change in month t defined as $X_t = (F_t \div L_{t-1} + I)$, and I_t the index of adjusted stocks in month t, the annual percentage change a_t – i.e. the change in the latest 12 months –may be calculated as follows:

(a)
$$a_t = ((X_t * X_{t-1} * X_{t-2} * X_{t-3} * X_{t-4} * X_{t-5} * X_{t-6} * X_{t-7} * X_{t-8} * X_{t-9} * X_{t-10} * X_{t-11}) - I) * I 00$$

(b)
$$a_r = (I_r \div I_{r-12} \dashv) * 100$$

Roundings may give rise to differences from the annual percentage changes shown in Table 2.4. The index of adjusted stocks is available with a higher level of precision on the ECB's website (http://www.ecb.int) on the 'Euro area statistics – download'' page (in csv file format), from which the exact percentage changes shown in Table 2.4 may be calculated.

For details see Findley, D., Monsell, B., Bell, W., Otto, M., and Chen, B.C. (1998), "New Capabilities and Methods of the X-12-ARIMA Seasonal Adjustment Program", Journal of Business and Economic Statistics, 16, 2, 127-152, or "X-12-ARIMA Reference Manual Version 0.2.2", (December 1998), Time Series Staff, Bureau of the Census, Washington, D.C.

ECB Monthly Bulletin • June 2000

General notes

The basis for the statistics compiled and published by the European Central Bank (ECB) was laid down in the document entitled the "Statistical requirements for Stage Three of Monetary Union (Implementation package)" which was made available to banking associations and others involved in statistical preparations for Stage Three by the European Monetary Institute (EMI) and the national central banks (NCBs) in July 1996. The "Implementation package" covers money and banking statistics, balance of payments statistics, international investment position statistics, financial accounts statistics, price and cost and other economic statistics.¹

The focus of these statistics is the euro area as a whole. More detailed and longer runs of data, with further explanatory notes, are available in a downloadable format (csv files) on the ECB's website (http://www.ecb.int), and new or expanded data will appear in the ECB Monthly Bulletin as they become available.

Because the composition of the ECU does not coincide with the currencies of the Member States which have adopted the single currency, pre-1999 amounts converted from the participating currencies into ECU at current ECU exchange rates are affected by movements in the currencies of Member States which have not adopted the euro. To avoid this effect in the monetary statistics, the pre-1999 data in Tables 2.1 to 2.8 are expressed in units converted from national currencies at the irrevocable euro exchange rates established on 31 December 1998. Unless indicated otherwise, price and cost statistics before 1999 are based on the data expressed in national currency terms.

Methods of aggregation and/or consolidation (including cross-country consolidation) have been used as appropriate.

As a general rule, the cut-off date for the statistics included in the ECB Monthly Bulletin is the day preceding the first meeting in the month of the Governing Council of the ECB. For this issue, it was 7 June 2000.

Recent data are often provisional and may be revised. Discrepancies between totals and their components may arise from rounding.

Monetary policy and financial statistics

Tables 1.1 to 1.5 show the consolidated financial statement of the Eurosystem, data on Eurosystem operations, statistics relating to minimum reserves, and the banking system's liquidity position. Monetary data relating to Monetary Financial Institutions (MFIs), including the Eurosystem, are shown in Tables 2.1 to 2.3. Table 2.3 is consolidated; inter-MFI positions within the euro area are not shown, but any difference between the sum total of such claims and liabilities as recorded is shown in column 13. Table 2.4 sets out monetary aggregates drawn from the consolidated MFI balance sheet; they also include some (monetary) liabilities of central government. Table 2.5 shows a quarterly sectoral and maturity analysis of loans by MFIs to euro area residents. Table 2.6 shows a quarterly analysis of deposits held by euro area residents with MFIs. Table 2.7 provides a quarterly analysis of MFI claims on and liabilities to non-residents of the euro area. Table 2.8 shows a quarterly currency analysis of certain MFI balance sheet items. A complete list of MFIs is published on the ECB's website. Details of the sector definitions are set out in the "Money and Banking Statistics Sector Manual: Guidance for the statistical classification of customers" (ECB, November 1999). The "Money and Banking Statistics Compilation Guide" (EMI, April 1998) explains recommended practices to be followed by the NCBs. From I January 1999 the statistical information is collected and compiled on the basis of the ECB Regulation concerning the consolidated balance sheet of the Monetary Financial Institutions sector (ECB/1998/16).

Money and banking statistics are the responsibility of the ECB at the European level; responsibility for balance of payments, international investment position and financial accounts statistics is shared with the European Commission (Eurostat); price and cost and other economic statistics are the responsibility of the European Commission (Eurostat).

Statistics on money market interest rates, long-term government bond yields and stock market indices (Tables 3.1 to 3.3) are produced by the ECB using data from wire services. For details concerning the statistics on retail bank interest rates (Table 3.4), see the footnote at the bottom of the relevant page.

Statistics on securities issues, redemptions and amounts outstanding are shown in Table 3.5, with a sectoral breakdown of issuers of euro-denominated securities, whether resident in the euro area or elsewhere, in Table 3.6. The totals (columns I, 7 and 14) in Table 3.6 are identical to the data on amounts outstanding (columns 8, 16 and 20), gross issues (columns 5, 13 and 17) and net issues (columns 7, 15 and 19) of euro-denominated securities in Table 3.5. The amounts outstanding of securities issued by MFIs (column 2) in Table 3.6 are broadly comparable with money market paper and debt securities issued as shown on the liabilities side of the aggregated MFI balance sheet in Table 2.8.3 (columns 2 and 10), although the coverage of the securities issues statistics is at present somewhat narrower. Pages 17-18 of the November 1999 issue of the ECB Monthly Bulletin give more detail on these statistics.

Prices and real economy indicators

The data presented in the ECB Monthly Bulletin are, with a few exceptions, produced by the European Commission (mainly Eurostat) and national statistical authorities. Euro area results are obtained by aggregating data for individual countries. As far as possible, the data are harmonised and comparable. However, the availability of comparable data is, as a general rule, better for the more recent periods than for earlier periods.

The Harmonised Index of Consumer Prices (HICP) for the euro area (Table 4.1) is available from 1995 onwards. Estimates for periods before 1995 based on national consumer price indices are not fully comparable. The index is

based on national HICPs that follow the same methodology in all euro area countries. Data from January 2000 include the cost of health and educational services; earlier data on the extended basis are, in general, not available. The HICP from January 2000 also covers spending by non-residents which had previously been excluded from the HICP in certain Member States.

With regard to statistics on national accounts (Tables 4.2 and 5.1), the implementation of the European System of Accounts 1995 (ESA 95) during 1999 and thereafter has begun to pave the way for fully comparable data, including quarterly summary accounts, across the euro area. Before 1999 the deflators of GDP in Table 4.2.2 are derived from national data in domestic currency. National accounts in this issue are based mainly on the ESA 95.

Table 5.2 shows selected other real economy indicators. The implementation of Council Regulation (EC) No. 1165/98 of 19 May 1998 concerning short-term statistics will enlarge the range of available euro area data.

Opinion survey data (Table/Chart 5.3) draw on the business and consumer surveys of the European Commission.

Employment data (Table 5.4) are based on the ESA 95. Since coverage of the euro area was not complete in time for this issue, some data are ECB estimates based on the information available. Unemployment rates conform to International Labour Organization (ILO) guidelines.

Financial accounts statistics

The "Implementation package" foresaw a need for detailed information covering the financial transactions and balance sheets for the euro area in order to complement monetary analysis and policy research. The aim is to provide a fairly full, though not complete, set of financial accounts for the euro area based on money and banking, balance of payments, capital market, non-MFI financial corporation and government finance statistics, and drawing also on the ESA 95 national accounts. Table 6 shows euro area aggregates based on national capital and financial accounts.

A more detailed and further harmonised set of statistics presenting financial accounts for the euro area is expected to appear in the ECB Monthly Bulletin later this year.

General government fiscal position

The general government fiscal position in the euro area is presented in Table 7 by reference to general government receipts, expenditure, saving, deficit and debt as a percentage of GDP. These data are aggregated by the ECB from harmonised data provided by the NCBs.

In addition, general government deficit and debt data are shown for individual euro area countries owing to their importance in the framework of the Stability and Growth Pact.

Balance of payments and international investment position of the euro area (including reserves), trade in goods and exchange rates

The concepts and definitions used in balance of payments statistics (Tables 8.1 to 8.5) and international investment position (i.i.p.) statistics generally conform to the 5th edition of the IMF Balance of Payments Manual (October 1993), to the ECB Guideline of I December 1998 (ECB/1998/17) on the statistical reporting requirements of the European Central Bank, and to Eurostat's documentation.

The euro area balance of payments is compiled by the ECB. Data up to December 1998 are expressed in ECU. The recent monthly figures for balance of payments statistics should be regarded as provisional. These data are revised with the publication of the detailed quarterly balance of payments data. Some earlier data have been partly estimated and may not be fully comparable with more recent observations. That is the case for the b.o.p. financial account before end-1998, the services account before end-1997, the monthly pattern of income for the years 1997 to 1999 and the i.i.p. at end-1997. Table 8.4.2 provides a sectoral breakdown of euro area purchasers of securities issued by non-residents of the euro area. It is not possible to show a sectoral breakdown of euro area issuers of securities acquired by non-residents.

The euro area i.i.p. (Table 8.6) is compiled on a net basis by aggregating national data. The i.i.p. is valued at current market prices with the exception of direct investment stocks, where book values are used to a large extent.

The outstanding amounts of the Eurosystem's international reserves and related assets are shown in Table 8.6.2. The corresponding reserves and related assets held by the ECB are shown separately in Table 8.6.3. The data in Tables 8.6.2 and 8.6.3 are in line with the recommendations for the IMF/BIS template on international reserves and foreign currency liquidity. Reserve assets data before end-1999 are not fully comparable with later observations.

Table 9 gives data on euro area external trade in goods, and indices – value, volume and unit value – for total exports and imports. The value index is calculated by the ECB. The volume index is derived from the unit value index provided by Eurostat and the value index. Owing to differences in definitions, classification, coverage and time of recording, external trade data, in particular imports, are not fully comparable with the goods item in the balance of payments statistics (Tables 8.1 and 8.2).

Table 10 shows nominal and real effective exchange rate indices for the euro. The bilateral rates shown are those against the 13 currencies used in the ECB's calculation of the "narrow" effective exchange rate of the euro. For all except the Hong Kong and Singapore dollars and the Korean won the bilateral rates are daily reference rates published by the ECB. Real indices (deflated by producer prices and unit labour costs in manufacturing respectively) for the group of 13 currencies are shown, together with one nominal and one real index (deflated by consumer prices) for a broader group of 39 currencies.

Other statistics

Statistics on other EU Member States (Table 11) follow the same principles as those for data relating to the euro area. Data for the United States and Japan contained in Tables/Charts 12.1 and 12.2 are obtained from national sources. Saving, investment and financing data for the United States and Japan (Table/Chart 12.2) are structured in the same way as the capital and financial flows data shown for the euro area in Table/Chart 6.

Chronology of monetary policy measures of the Eurosystem'

4 January 2000

The ECB announces that on 5 January 2000 the Eurosystem will conduct a liquidity-absorbing fine-tuning operation with same-day settlement. This measure aims at restoring normal liquidity conditions in the money market after the successful transition to the year 2000.

5 January 2000

The Governing Council of the ECB decides that the interest rates on the main refinancing operations, the marginal lending facility and the deposit facility will remain unchanged at 3.0%, 4.0% and 2.0% respectively.

15 January 2000

At the request of the Greek authorities, the ministers of the euro area Member States, the ECB and the ministers and central bank governors of Denmark and Greece decide, following a common procedure, to revalue the central rate of the Greek drachma in the exchange rate mechanism (ERM II) by $3\frac{1}{2}$ %, with effect from 17 January 2000.

20 January 2000

The Governing Council of the ECB decides that the interest rates on the main refinancing operations, the marginal lending facility and the deposit facility will remain unchanged at 3.0%, 4.0% and 2.0% respectively.

It also announces that the Eurosystem intends to allot an amount of \in 20 billion for each of the longer-term refinancing operations to be conducted in the first half of 2000. This amount takes into consideration the expected liquidity needs of the banking system of the euro area in the first half of 2000 and the desire of the Eurosystem to continue to provide the bulk of its refinancing of the financial sector through its main refinancing operations.

3 February 2000

The Governing Council of the ECB decides to raise the interest rate on the main refinancing operations of the Eurosystem by 0.25 percentage point to 3.25%, starting from the operation to be settled on 9 February 2000. In addition, it decides to increase the interest rates on both the marginal lending facility and the deposit facility by 0.25 percentage point, to 4.25% and 2.25% respectively, both with effect from 4 February 2000.

17 February, 2 March 2000

The Governing Council of the ECB decides that the interest rates on the main refinancing operations, the marginal lending facility and the deposit facility will remain unchanged at 3.25%, 4.25% and 2.25% respectively.

16 March 2000

The Governing Council of the ECB decides to raise the interest rate on the main refinancing operations of the Eurosystem by 0.25 percentage point to 3.5%, starting from the operation to be settled on 22 March 2000. In addition, it decides to increase the interest rates on both the marginal lending facility and the deposit facility by 0.25 percentage point, to 4.5% and 2.5% respectively, with effect from 17 March 2000.

30 March, 13 April 2000

The Governing Council of the ECB decides that the interest rates on the main refinancing operations, the marginal lending facility and the deposit facility will remain unchanged at 3.5%, 4.5% and 2.5% respectively.

The chronology of monetary policy measures of the Eurosystem taken in 1999 can be found on pages 176 to 179 of the ECB Annual Report 1999.

27 April 2000

The Governing Council of the ECB decides to raise the interest rate on the main refinancing operations of the Eurosystem by 0.25 percentage point to 3.75%, starting from the operation to be settled on 4 May 2000. In addition, it decides to increase the interest rates on both the marginal lending facility and the deposit facility by 0.25 percentage point, to 4.75% and 2.75% respectively, both with effect from 28 April 2000.

11 May 2000

The Governing Council of the ECB decides that the interest rates on the main refinancing operations, the marginal lending facility and the deposit facility will remain unchanged at 3.75%, 4.75% and 2.75% respectively.

25 May 2000

The Governing Council of the ECB decides that the interest rates on the main refinancing operations, the marginal lending facility and the deposit facility will remain unchanged at 3.75%, 4.75% and 2.75% respectively.

8 June 2000

The Governing Council of the ECB decides to raise the interest rate on the main refinancing operations of the Eurosystem by 0.50 percentage point to 4.25% and to apply this in the two operations (which will be conducted as fixed rate tenders) to be settled on 15 and 21 June 2000. In addition, it decides to increase the interest rates on both the marginal lending facility and the deposit facility by 0.50 percentage point, to 5.25% and 3.25% respectively, both with effect from 9 June 2000.

It also announces that, starting from the operation to be settled on 28 June 2000, the main refinancing operations of the Eurosystem will be conducted as variable rate tenders, applying the multiple rate auction procedure. The Governing Council decides to set a minimum bid rate for these operations equal to 4.25%. The switch to variable rate tenders in the main refinancing operations is not intended as a further change in the monetary policy stance of the Eurosystem, but as a response to the severe overbidding which has developed in the context of the current fixed rate tender procedure.

The TARGET (Trans-European Automated Real-time Gross settlement Express Transfer) system

TARGET closing days in 2001

In 2001, in addition to Saturdays and Sundays, TARGET will be closed on New Year's Day, Good Friday, Easter Monday, I May (Labour Day), Christmas Day, 26 December and 31 December. This is the same as the calendar adopted for 2000, with the exception of one additional closing day on 31 December in order to safeguard the smooth conversion of retail payment systems and internal bank systems to the euro. On 31 December 2001 TARGET as a whole, including all the national real-time gross settlement (RTGS) systems, will be closed. However, this day will not necessarily be a bank holiday as a consequence of this decision.

The Governing Council will allow national central banks to keep their RTGS systems open

for limited domestic operations as follows: the Banca d'Italia and the Nationale Bank van België/ Banque Nationale de Belgique on Good Friday (13 April 2001), the Banco de España on Easter Monday (16 April 2001) and on 26 December 2001, the Central Bank of Ireland and De Nederlandsche Bank on Labour Day (1 May 2001). However, no cross-border payments will be processed on TARGET closing days.

TARGET closing days will not be settlement days for the euro money market or for foreign exchange transactions involving the euro. The EONIA (euro overnight index average) will not be published on the TARGET closing days. Furthermore, the correspondent central banking model (CCBM) for the cross-border use of collateral will be closed.

1) The PNS replaced the Système Net Protégé (SNP) on 19 April 1999.

By the end of 2000 the Eurosystem intends to establish a long-term calendar of TARGET operating days to apply as from 2002 until further notice.

Payment flows in TARGET

The positive trend, in particular with regard to cross-border TARGET payments, continued in the first quarter of 2000. Compared with the fourth quarter of 1999, in this period the number of cross-border payments increased by 17% (37,326 payments as a daily average) and the value increased by around 7% (\in 413 billion as a daily average). The peak day for TARGET cross-border activity was 31 March 2000. On this day 53,563 payments, representing a value

of \in 552 billion, were processed. The share of customer payments in total cross-border TARGET payments increased slightly and now stands at around 31% in terms of volume and 3.1% in terms of value. In the first three months of 2000 the average value of customer payments stood at \in 1.1 million; for interbank payments the average value was \in 15.6 million.

In the first quarter of 2000 the number of payments processed in TARGET as a whole, i.e. cross-border and domestic payments taken together, was nearly 180,000 as a daily average, representing a value of around \in 1 trillion.

Further information on the TARGET system is available in the TARGET section of the ECB's website (http://www.ecb.int).
