Financial Times, June 16, 2021

Why is Wall Street's fear gauge so low?

Investors urged to have 'eyes wide open about what is coming next'

- transitory inflation narrative of the Federal Reserve
- "higher downside risk to the news flow than usual"

Motivation	A New Stylized Fact	(MF) ² GARCH	V-Lab	Properties	News Effects	Forecasting	Conclusions
•	0000	00000	000	000000	000	000	0
Motiv	ation						

- strong empirical evidence that the conditional variance of stock returns consists of several components (Ding and Granger, 1996, Engle and Lee, 1999, Corsi, 2009)
- recent GARCH-type models assume multiplicative short- and long-term components: Spline GARCH (Engle and Rangel, 2008), GARCH-MIDAS (Engle et al., 2013)
- we propose a new approach for modelling the long-term component:
 - we document that the daily forecast errors of one-component GARCH models are predictable when averaged at a lower frequency
 - due to long-term volatility cycles that are not captured by standard $\ensuremath{\mathsf{GARCH}}$ models
 - Iong-term component: learning from past forecast errors
 - Multiplicative Factor Multi Frequency GARCH (MF)² GARCH
 - instantaneous/short-run response to news
 - long-term forecasts
 - Volatility Lab: real-time estimates and forecasts of financial volatility

Motivation	A New Stylized Fact	(MF) ² GARCH	V-Lab	Properties	News Effects	Forecasting	Conclusions
0	●000	00000	000	000000	000	000	0

GJR GARCH(1,1) for daily returns:

$$r_{i,t} = \sqrt{\tilde{h}_{i,t}}\zeta_{i,t},$$

where $\tilde{h}_{i,t}$ denotes the conditional variance and the $\zeta_{i,t}$ are *i.i.d.* with mean zero and variance one.

- low frequency period t = 1, ..., T (monthly or quarterly)
- high frequency period i, n days within in each period t

Misspecification testing:

• testing for an omitted multiplicative volatility component

$$\zeta_{i,t} = \sqrt{\tau_t} Z_{i,t}$$
, where the $Z_{i,t}$ are *i.i.d*.

 Lundbergh and Teräsvirta (2002): n = 1 Conrad and Schienle (2020): explanatory variables, n ≥ 1

Tests are based on the (fitted) squared standardized residuals

$$\zeta_{i,t}^2 = \frac{r_{i,t}^2}{\tilde{h}_{i,t}}$$

What if τ_t varies smoothly over time?

We will focus on

$$ilde{V}_t = rac{1}{n}\sum_{i=1}^n rac{r_{i,t}^2}{ ilde{h}_{i,t}}.$$

Interpretation: average of the standardized volatility forecast errors within low-frequency period t.

Example: daily S&P 500 log-returns for the period January 1971 to June 2020.

$$ilde{h}_{i,t} = \underbrace{0.017}_{(0.003)} + \underbrace{(0.022}_{(0.007)} + \underbrace{0.110}_{(0.014)} \mathbf{1}_{\{r_{i-1,t} < 0\}} \mathbf{1}_{i-1,t} + \underbrace{0.905}_{(0.009)} ilde{h}_{i-1,t}$$

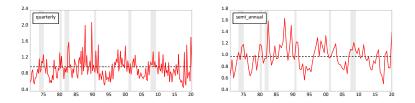

Figure 1: A GJR GARCH(1,1) is estimated for the S&P 500 using daily return data for the January 1971 to June 2020 period. The figure shows $\tilde{V}_t = n^{-1} \sum_{i=1}^n r_{i,t}^2 / \tilde{h}_{i,t}$ at a quarterly (left panel) and semi-annual (right panel) frequency. Grey shaded areas represent NBER recession periods.

- low-frequency forecast errors predictable (not *i.i.d.*)
- low-frequency forecast errors are counter-cyclical

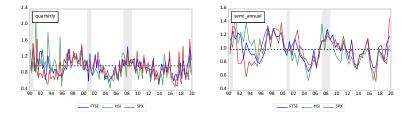

Figure 2: Volatility forecast errors for international stock markets.

• Engle and Campos-Martins (2020): Geopolitical events

The (MF)² GARCH

We focus on the model with daily τ_t (i.e. we assume that n = 1).

$$r_t = \sigma_t Z_t = \sqrt{h_t \tau_t} Z_t.$$

Assumption 1

Let Z_t be i.i.d. with $\mathbf{E}[Z_t] = 0$, $\mathbf{E}[Z_t^2] = 1$ and $1 < \kappa < \infty$, where $\kappa = \mathbf{E}[Z_t^4]$.

Short-term volatility component

$$h_{t} = (1 - \phi) + \left(\alpha + \gamma \mathbf{1}_{\{r_{t-1} < 0\}}\right) \frac{r_{t-1}^{2}}{\tau_{t-1}} + \beta h_{t-1},$$
(1)

where $\phi = \alpha + \gamma/2 + \beta$.

Motivation	A New Stylized Fact	(MF) ² GARCH	V-Lab	Properties	News Effects	Forecasting	Conclusions
0	0000	00000	000	000000	000	000	0
$(MF)^2$	² GARCH						

Assumption 2

The parameters of the short-term GJR-GARCH component satisfy the conditions $\alpha > 0$, $\alpha + \gamma > 0$, $\beta > 0$ and $\phi = \alpha + \gamma/2 + \beta < 1$.

Hence,

$$\frac{r_t}{\sqrt{\tau_t}} = \sqrt{h_t} Z_t,$$

follows a covariance stationary GJR GARCH with $\mathbf{E}[h_t Z_t^2] = \mathbf{E}[h_t] = 1$.

How to specify τ_t ?

Consider the squared deGARCHed returns:

$$V_t = \frac{r_t^2}{h_t} = \tau_t Z_t^2.$$

If the GARCH component fully captures the conditional heteroskedasticity, then the V_t are *i.i.d.*

Motivation	A New Stylized Fact	(MF) ² GARCH	V-Lab	Properties	News Effects	Forecasting	Conclusions
0	0000	00000	000	000000	000	000	0
$(MF)^2$	² GARCH						

Long-term volatility component

We parameterize the long-term component as

$$\tau_t = \lambda_0 + \lambda_1 V_{t-1}^{(m)} + \lambda_2 \tau_{t-1},$$

where

$$V_{t-1}^{(m)} = rac{1}{m} \sum_{j=1}^m V_{t-j} = rac{1}{m} \sum_{j=1}^m rac{r_{t-j}^2}{h_{t-j}}.$$

interpretation:

- $V_{t-1}^{(m)}$ as rolling window measure of recent forecast performance of the GARCH component
- MEM(1, m) with the restriction that the m "ARCH" coefficients are given by λ_1/m .
- τ_t as scaling factor: scales volatility up/down if the short-term component underestimated/overestimated volatility in the recent past

Assumption 3

The parameters in the long-term component satisfy the conditions $\lambda_0 > 0$, $\lambda_1 > 0$, $\lambda_2 > 0$ and $\lambda_1 + \lambda_2 < 1$.

Under Assumptions 1 and 3 it holds that

$$\begin{split} \mathbf{\mathsf{E}}[V_t | \mathcal{F}_{t-1}] &= \tau_t \\ \mathbf{\mathsf{E}}[V_t] &= \lambda_0 / (1 - \lambda_1 - \lambda_2) \end{split}$$

• $V_t = \tau_t Z_t^2$ is a covariance stationary MEM

We refer to this parametrization as $(MF)^2$ GARCH-rw-m.

- can be estimated by QMLE
- select m by BIC

Unconditional variance

Theorem 1: Let Assumptions 1-3 be satisfied. If the $(MF)^2$ GARCH-rw-*m* process, $(r_t)_{t\in\mathbb{Z}}$, is covariance stationary, then

$$\Gamma_m = \left(\lambda_1 \frac{1}{m} \phi_\kappa + \lambda_2 \phi\right) + \lambda_1 \phi_\kappa \frac{1}{m} \sum_{j=2}^m \phi^{j-1} < 1$$
(2)

with $\phi_\kappa = (\alpha + \gamma/2)\kappa + \beta$. The unconditional variance of the daily returns is given by

$$\mathbf{Var}[r_t] = \frac{\lambda_0 + \frac{\lambda_0}{1 - \lambda_1 - \lambda_2} (1 - \phi)(\lambda_1 + \lambda_2) + \Delta_m}{1 - \Gamma_m},\tag{3}$$

where

$$\Delta_m = (1-\phi)\lambda_1\phirac{\lambda_0}{1-\lambda_1-\lambda_2}\left(rac{m-1}{m}+rac{1}{m}\sum_{j=2}^m\sum_{k=1}^{j-2}\phi^k
ight).$$

- feedback: short- and long-term component are correlated
- Var[r_t] depends on κ (\nearrow) and m (\searrow)

News impact function

NIC for GJR GARCH

$$NIC_{t+1}^{GA} = \tilde{h}_{t+1}(r_t|\tilde{h}_t) = A_t^{GA} + (\alpha + \gamma \mathbf{1}_{\{r_t < 0\}})r_t^2,$$

Effect of r_t does not depend on current level of volatility!

At odds with empirical observation for options implied volatility:

"..., if VIX indicates the market is going to be volatile it may not react too much when the market is volatile. And if VIX indicates the market is expected to be less volatile, if we do get high volatility, VIX adjusts accordingly." (Rhoades, 2020, p.60)

NIC for (MF)² GARCH: the effect of r_t depends on σ_t^2 , h_t and τ_t

Motivation	A New Stylized Fact	(MF) ² GARCH	V-Lab	Properties	News Effects	Forecasting	Conclusions

Relation to other multiplicative component models

- GARCH-type for volatility
 - Spline-GARCH
 - returns are non-stationary, long-term forecasting?
 - GARCH-MIDAS
 - Conrad and Loch (2015), Conrad and Kleen (2020)
 - long-term: term spread, housing starts, SPF expectations for output growth, corporate profits, unemployment rate
 - short-term: NFCI, VIX
 - how to select relevant variables?
 - not dynamically complete
 - no feedback from short- to long-term component
- intraday volume: Composite-MEM (Brownlees et al., 2011)
- realized volatilities: Component-MEM (Amendola et al., 2020)

Concl	usions						

(MF)² GARCH

- exploits predictability in standardized volatility forecast errors
- feedback from short- to long-term component
- properties: stationary returns, news impact depends on current volatility, dynamically complete, simple to estimate by QMLE
- empirical evidence: (MF)² GARCH ...
 - is preferred to nested GJR GARCH
 - response to extreme events is more realistic than in one-component GARCH
 - outperforms standard models at intermediate and long forecast horizons
- applications
 - long-run value at risk (SRISK), portfolio choice
